

The Higgs: Discovery at the LHC

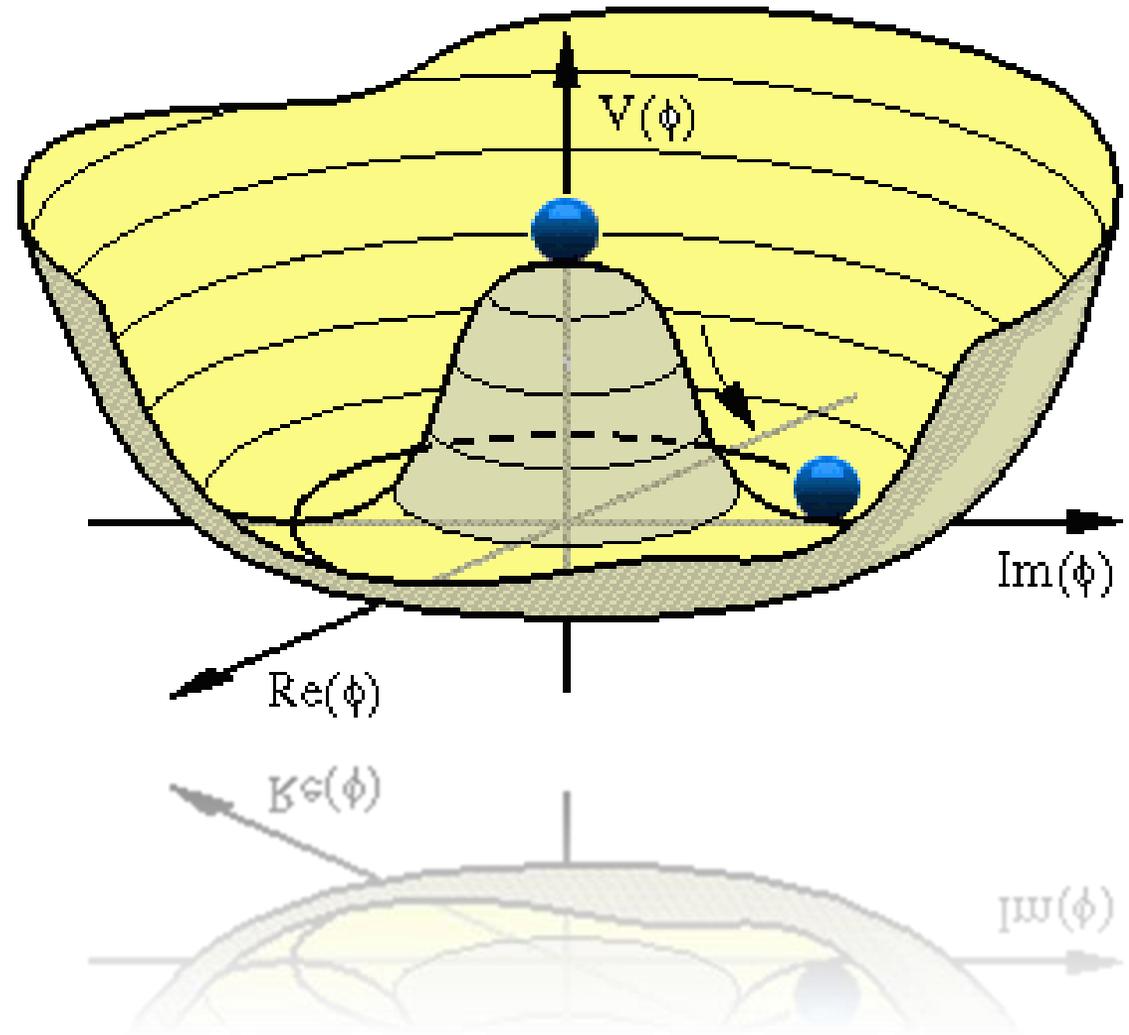

The Discovery of the Higgs Boson

Toni Baroncelli

Higgs Searches at LEP

*The Higgs, the
(once!) missing
piece of the
Standard Model*

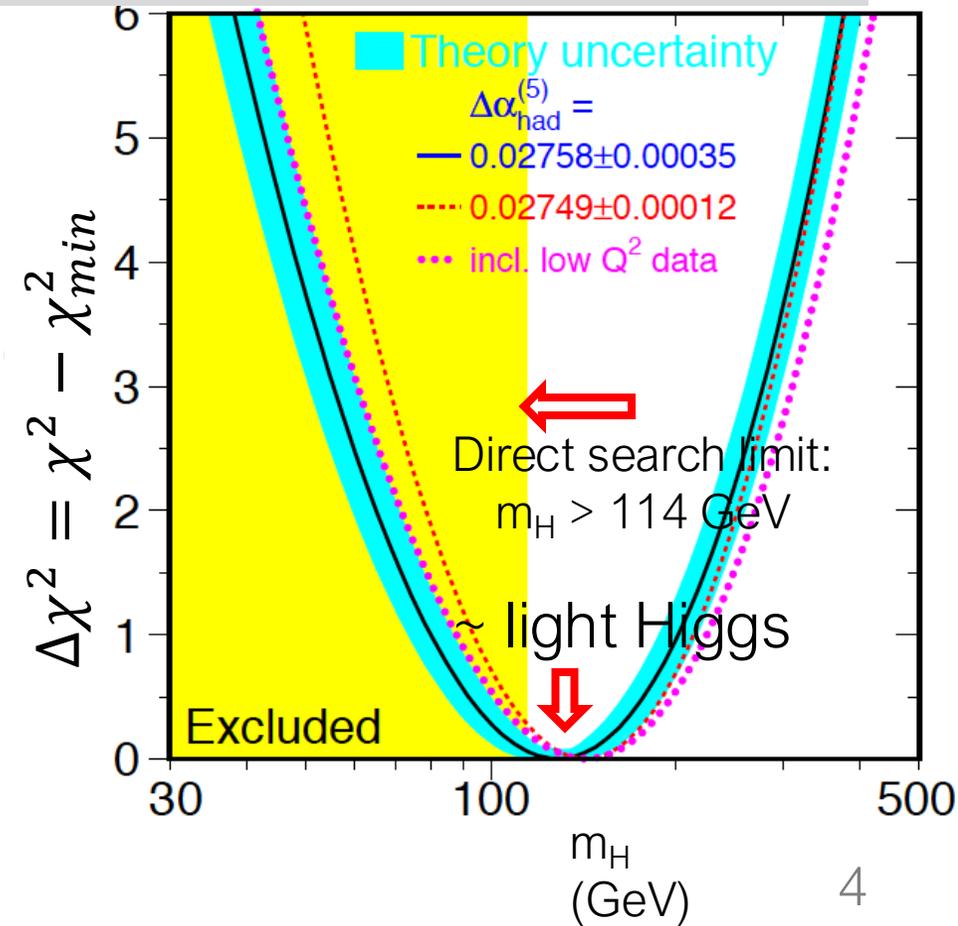

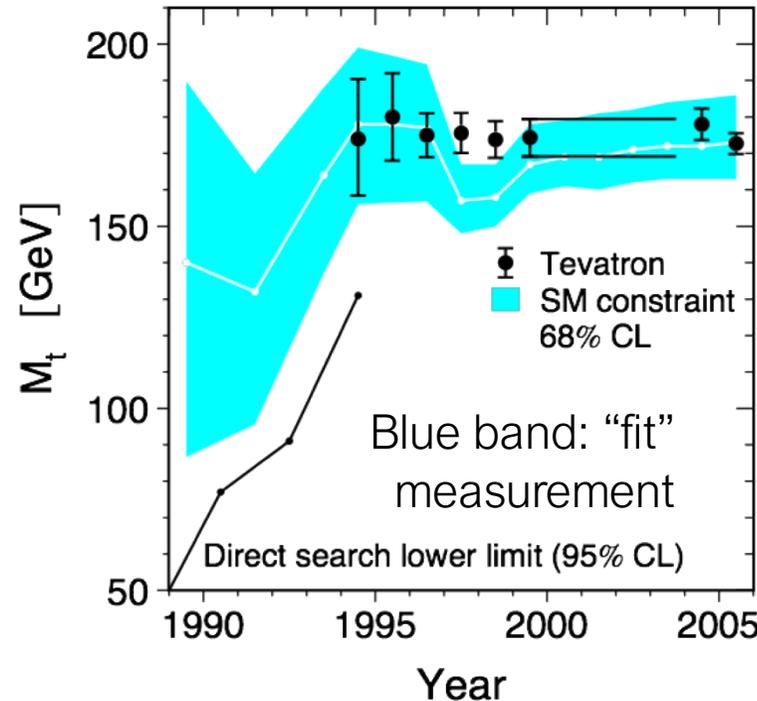

m_t and $m_H \rightarrow EW$ fits

There are very many EW measurements: cross sections, asymmetries and many others.

Some diagrams contain loops where top and Higgs bosons circulate \rightarrow slightly modify observables \rightarrow indication on top mass and Higgs mass before their discoveries

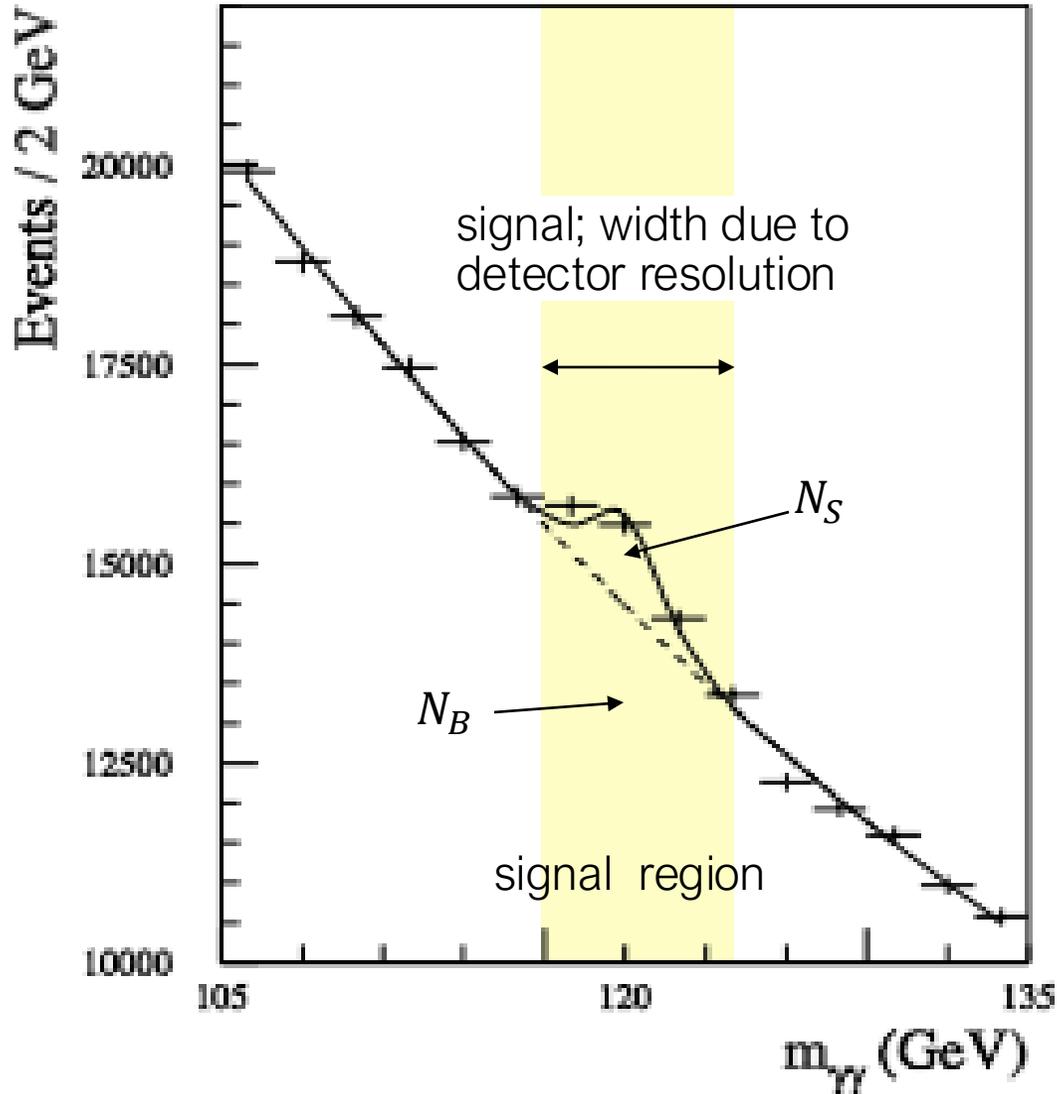

Summer 2004

Higgs and the Tevatron: Reminder on Discoveries

The Higgs Boson was also searched for at the Tevatron. Without success! Why?

Signal significance:

$$S = \frac{N_S}{\sqrt{N_B + N_S}} \approx \frac{N_S}{\sqrt{N_B}}$$

N_S : # signal events

N_B : # background events

In the “signal region”

Kinematically out of reach?

By “convention” a discovery is claimed when the significance

$$S > 5:$$

This means that the signal

$$N_S = N_{\text{tot}} - N_B$$

is 5 times larger than statistical uncertainty on $N_B + N_S$ → the probability of a fluctuation is very small: the Gaussian probability that upward fluctuation by more than 5σ is observed is

$$P_{5\sigma} = 10^{-7}$$

The sensitivity to a signal increases with increasing statistics

Complications of Real Life: Background

1. Choose channels with low SM background

not possible: $H \rightarrow bb$... without associated production ... (VH mode, $V=W,Z$)

possible: $H \rightarrow \gamma\gamma$... despite of small branching ratio ...

$H \rightarrow ZZ$... with at least one Z decaying leptonically ...

$H \rightarrow WW$... large signal and large background ...

2. Optimize detector resolution

Example: mass resolution σ_m increases by a factor of 2;

thus: peak region has to be increased by a factor 2 and

number N_B of background events increases by factor of 2

$S = N_s/\sqrt{N_B}$ decreases by $\sqrt{2}$

$$S \sim \frac{1}{\sqrt{\sigma_m}}$$

3. Recorded luminosity \mathcal{L}

Signal: $N_s \sim \mathcal{L}$

Background: $N_B \sim \mathcal{L}$

$$S \sim \frac{1}{\sqrt{\mathcal{L}}}$$

| Decay channel | Mass resolution |
|---|-----------------|
| $H \rightarrow \gamma\gamma$ | 1-2% |
| $H \rightarrow ZZ \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ | 1-2% |
| $H \rightarrow W^+W^- \rightarrow \ell^+\nu_\ell\ell'^-\bar{\nu}_{\ell'}$ | 20% |
| $H \rightarrow b\bar{b}$ | 10% |
| $H \rightarrow \tau^+\tau^-$ | 15% |

→ *Need a good detector and a lot of Luminosity*

Higgs Decay Channels Investigated by CDF & D0

CDF

Higgs Production Mechanisms at Hadron Colliders

Loop with circulating **tops**, other quarks contribute much less

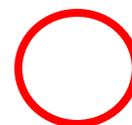

Gluon-gluon fusion

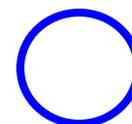

Vector bosons fusion

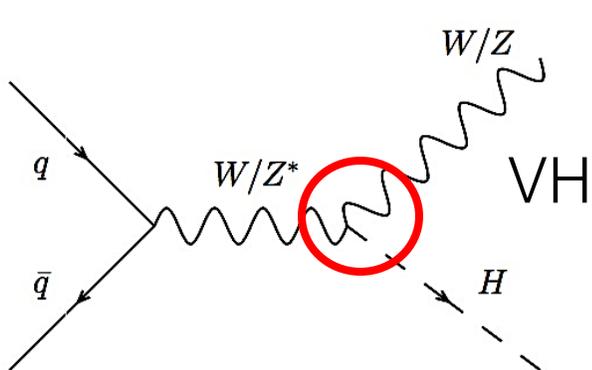

Higgs couples to massive particles, cannot couple directly to gluons and photons

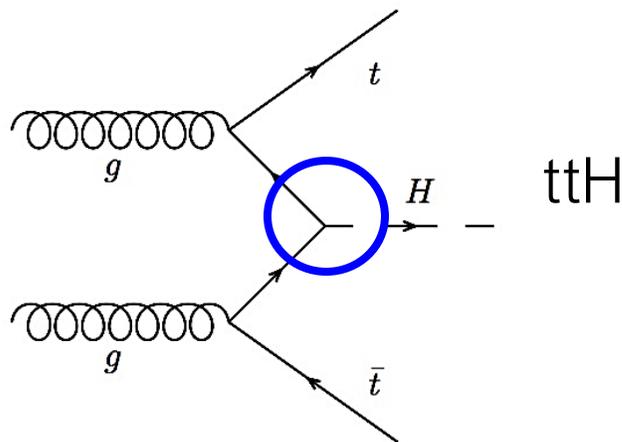

Vertex with Higgs & bosons

Vertex with Higgs & fermions

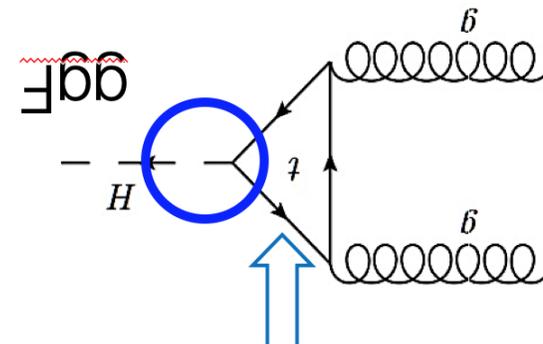

Associated production

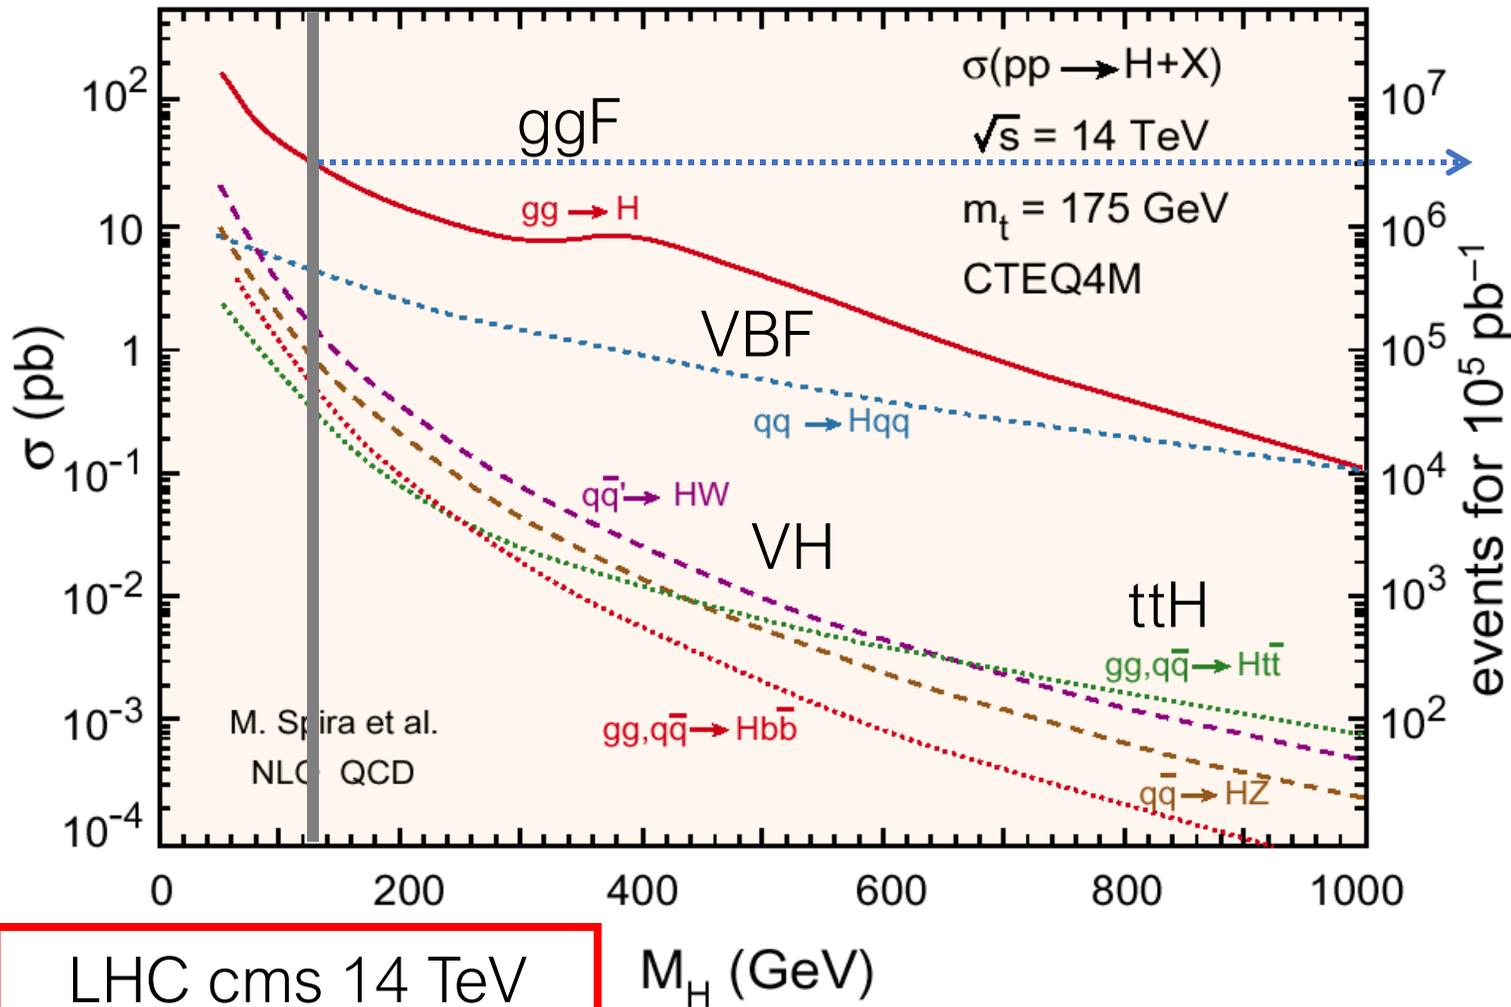

$t\bar{t}$ fusion

We will find the same vertices also in the Higgs decay!

Higgs Search at the LHC

Higgs production cross-section at centre-of-mass energies of 14 TeV, as a function of m_H .

Different production mechanisms are shown

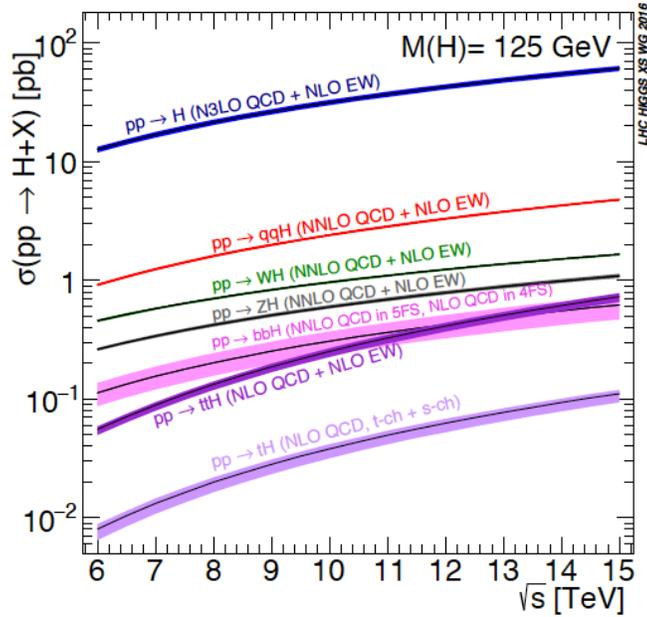

$$10^5 \text{ pb}^{-1} = 100 \text{ fb}^{-1}$$

'Millions' of 125 GeV Higgs produced by the ggF mechanism at 14 TeV for 100 fb^{-1} total luminosity

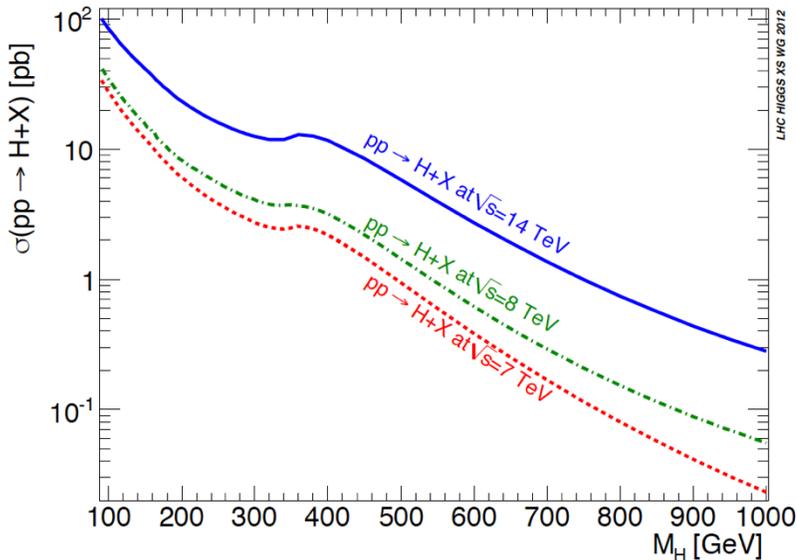

Acceptance and efficiency reduces this number drastically!

Cross Section vs \sqrt{s} for a 125 GeV Higgs

| \sqrt{s} (TeV) | Production cross section (in pb) for $m_H = 125$ GeV | | | | | | total | Calculation |
|------------------|--|-------------------------------------|------------------------------------|-------------------------------------|---------------------------------------|------|------------|-------------|
| | ggF | VBF | WH | ZH | $t\bar{t}H$ | | | |
| 1.96 | 0.95 ^{+17%} _{-17%} | 0.065 ^{+8%} _{-7%} | 0.13 ^{+8%} _{-8%} | 0.079 ^{+8%} _{-8%} | 0.004 ^{+10%} _{-10%} | 1.23 | Tevatron | |
| 7 | 16.9 ^{+5%} _{-5%} | 1.24 ^{+2%} _{-2%} | 0.58 ^{+3%} _{-3%} | 0.34 ^{+4%} _{-4%} | 0.09 ^{+8%} _{-14%} | 19.1 | LHC Run 1 | |
| 8 | 21.4 ^{+5%} _{-5%} | 1.60 ^{+2%} _{-2%} | 0.70 ^{+3%} _{-3%} | 0.42 ^{+5%} _{-5%} | 0.13 ^{+8%} _{-13%} | 24.2 | | |
| 13 | 48.6 ^{+5%} _{-5%} | 3.78 ^{+2%} _{-2%} | 1.37 ^{+2%} _{-2%} | 0.88 ^{+5%} _{-5%} | 0.50 ^{+9%} _{-13%} | 55.1 | LHC Run 2 | |
| 14 | 54.7 ^{+5%} _{-5%} | 4.28 ^{+2%} _{-2%} | 1.51 ^{+2%} _{-2%} | 0.99 ^{+5%} _{-5%} | 0.60 ^{+9%} _{-13%} | 62.1 | LHC Run HL | |

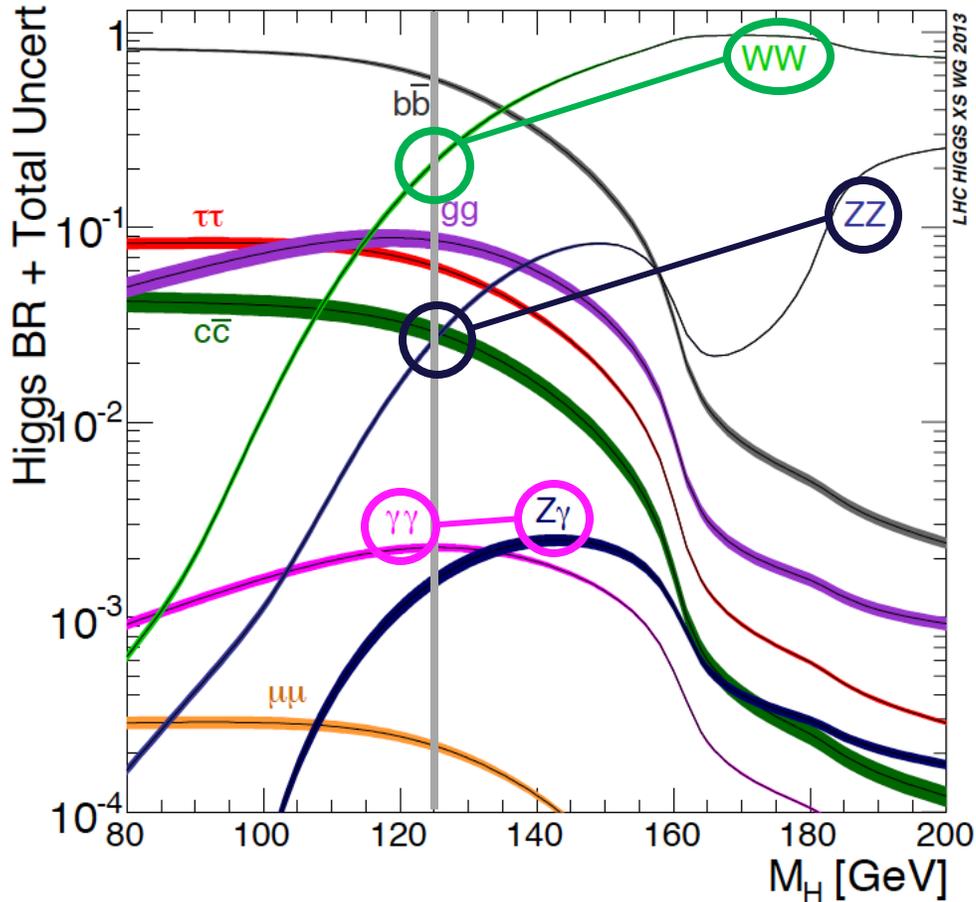

- Relative ratios between different production modes is \sim constant at LHC energies: ggF \rightarrow VBF \rightarrow WH \rightarrow $t\bar{t}H$
- The total cross section for the production of an Higgs of 125 GeV increases significantly with centre-of-mass energy

$$\frac{\sigma_{Higgs(125 GeV)}^{\sqrt{s}=1.96 TeV}}{\sigma_{Higgs(125 GeV)}^{\sqrt{s}=13 TeV}} = 2.2\%$$

Tevatron: ggF then WH
LHC: ggF then VBF

Higgs Decay Branching Fractions

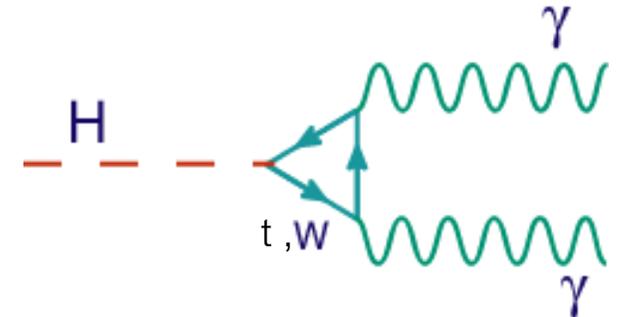

For $m_H = 125$ GeV: $H \rightarrow bb, WW, gg, \tau\tau$
 For $m_H > 160$ GeV: $H \rightarrow WW, ZZ$ dominant

Discovery driven by significance of different channels

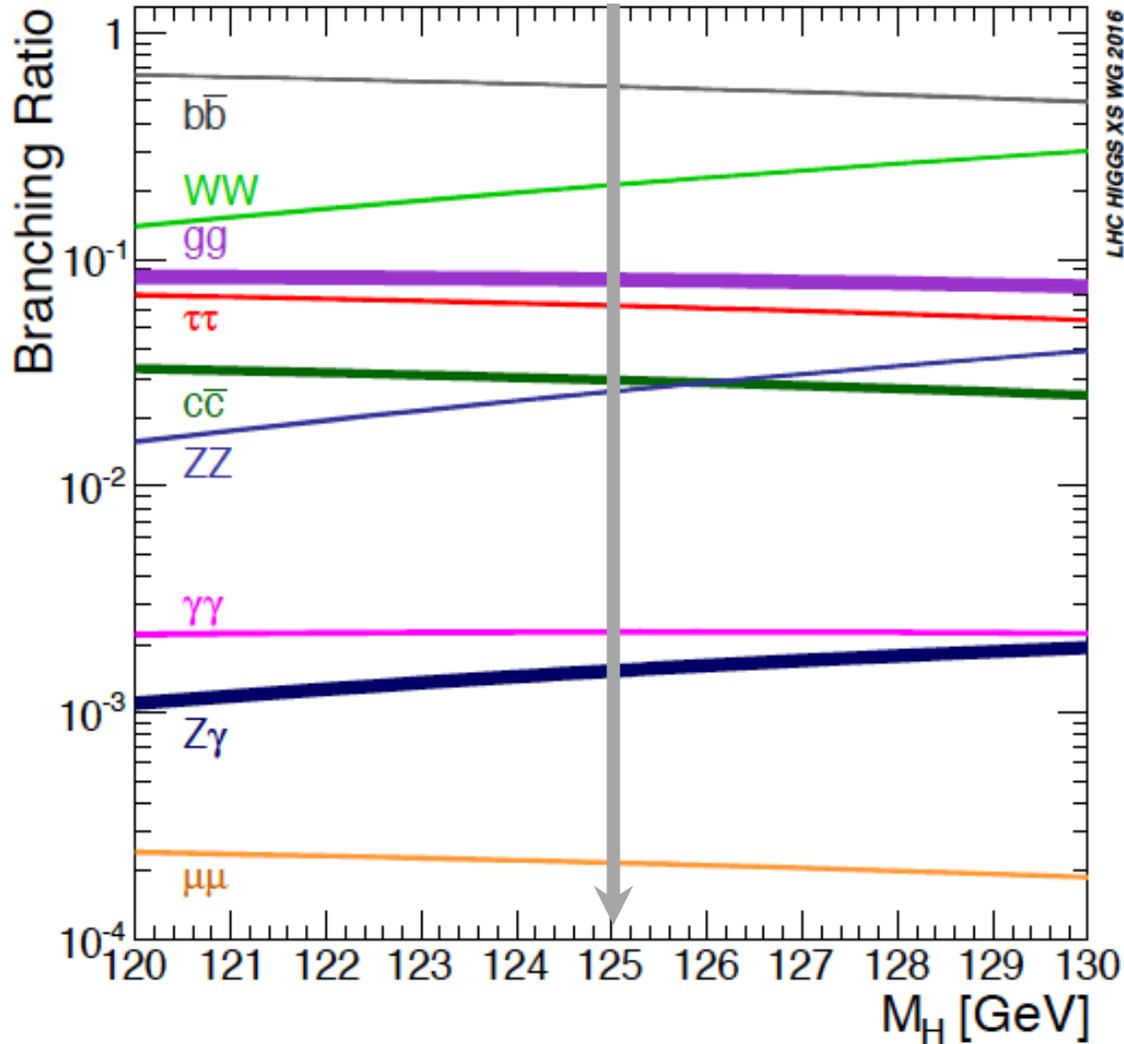

What really counts is how well one can distinguish a Higgs signal from the background

Example: the decay of the Higgs into a pair of photons is very small ($H \rightarrow WW$ is ~ 100 times larger than $H \rightarrow \gamma\gamma$), however the distinct topology it generates made it very important in the Higgs discovery

- Channels used for the Higgs discovery:
- ZZ to 4 leptons
 - Two photons
 - Two WW to leptons and neutrinos (a bit late!)

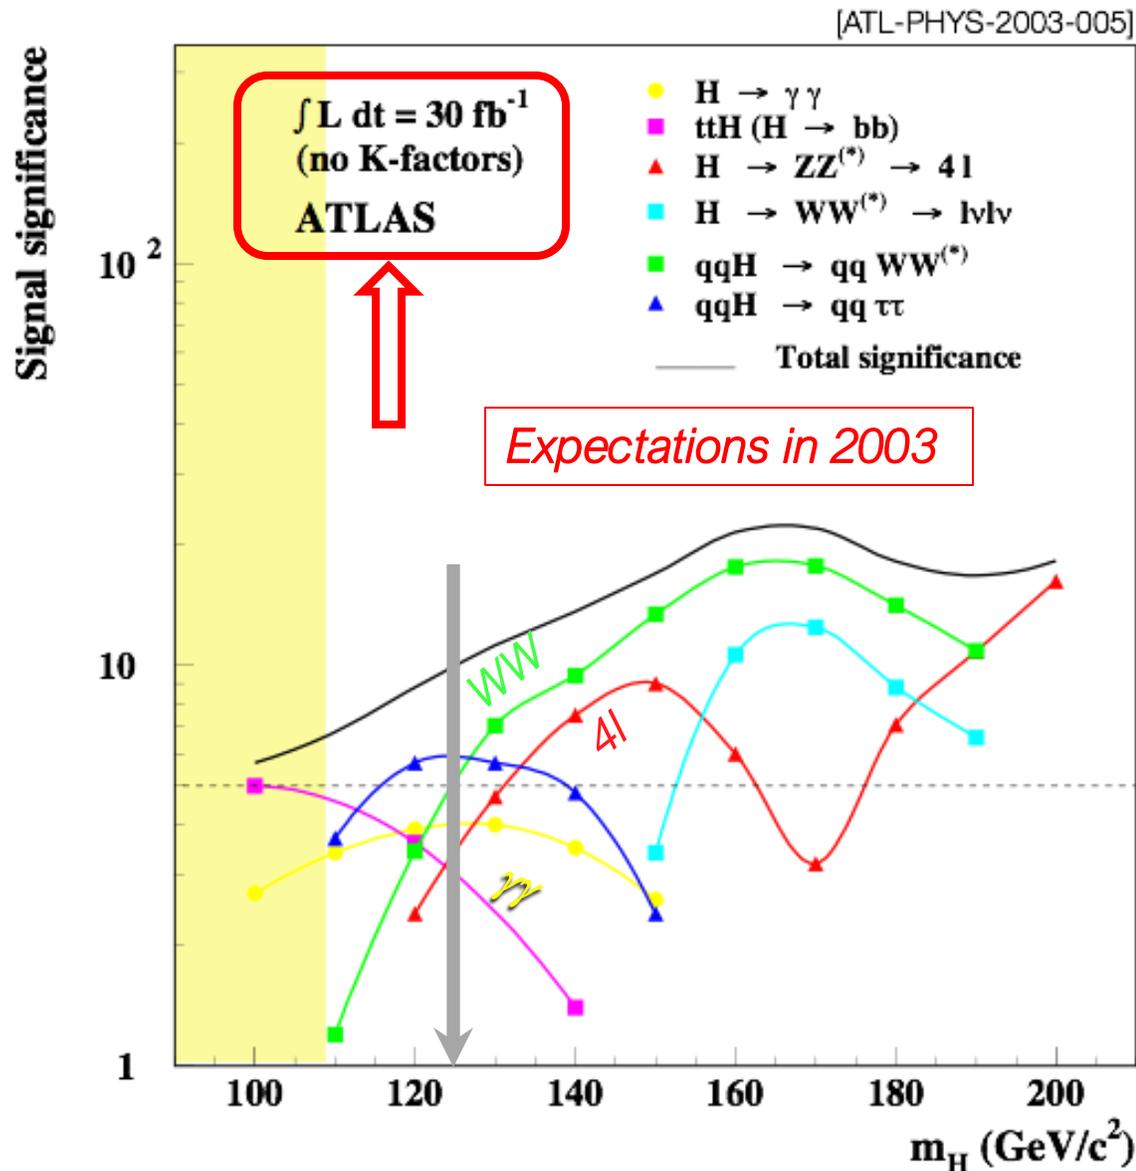

Zooming the Branching Ratios of the Higgs

$m_H = 125 \text{ GeV}$

| Decay channel | Branching ratio | Rel. uncertainty |
|------------------------------|-----------------------|------------------|
| $H \rightarrow \gamma\gamma$ | 2.27×10^{-3} | +5.0% -4.9% |
| $H \rightarrow ZZ$ | 2.62×10^{-2} | +4.3% -4.1% |
| $H \rightarrow W^+W^-$ | 2.14×10^{-1} | +4.3% -4.2% |
| $H \rightarrow \tau^+\tau^-$ | 6.27×10^{-2} | +5.7% -5.7% |
| $H \rightarrow b\bar{b}$ | 5.84×10^{-1} | +3.2% -3.3% |
| $H \rightarrow Z\gamma$ | 1.53×10^{-3} | +9.0% -8.9% |
| $H \rightarrow \mu^+\mu^-$ | 2.18×10^{-4} | +6.0% -5.9% |

Pre-Discovery Discovery Potential

Statement in 2003

- Full mass range can already be covered after a few years at low luminosity
- Several channels available over a large range of masses

• Low mass discovery requires combination of three of the most demanding channels

- Comparable situation for the CMS experiment

Prediction almost correct:

- $\gamma\gamma$, ZZ to 4 leptons, WW to $l\nu l\nu$ (higgs to $qq\tau\tau$ not used)
- Combination of channels

Higgs Terms in the Lagrangian

$$\mathcal{L} = -g_{Hf\bar{f}}\bar{f}fH + \frac{g_{HHH}}{6}H^3 + \frac{g_{HHHH}}{24}H^4 + \delta_V V_\mu V^\mu \left(g_{HVV}H + \frac{g_{HHVV}}{2}H^2 \right)$$

linear

quadratic

$$g_{Hf\bar{f}} = \frac{m_f}{v}$$

$$g_{HVV} = \frac{2m_V^2}{v}$$

$$g_{HHVV} = \frac{2m_V^2}{v^2}$$

$$g_{HHH} = \frac{3m_H^2}{v}, \quad g_{HHHH} = \frac{3m_H^2}{v^2}$$

$V = W^\pm$ or Z

$\delta W = 1, \delta Z = 1/2$

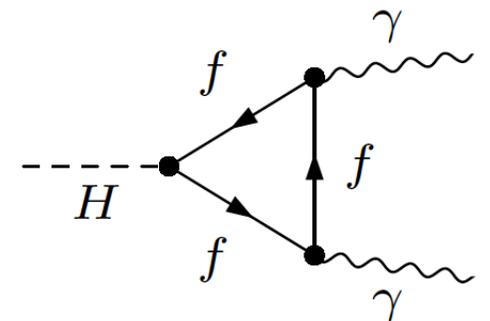

- The dominant mechanisms for Higgs boson production and decay involve the coupling of H to W, Z and/or the third generation quarks and leptons.

Coupling to bosons (W or Z) $\propto m_V^2$

Coupling to fermions $\propto m_f$

- The Higgs coupling to photons is generated by loops
 - virtual W^+W^- pair provides the dominant contribution
 - virtual tt pair is subdominant.

- The Higgs coupling to gluons, is induced by a one-loop graph: H couples to a virtual tt pair.

The Story of the Higgs (Discovery) in one Slide

- Indirect bounds on m_H from global EW fits : two decades at LEP, SLC, Tevatron suggest a ~light Higgs

$$m_H = 89^{+35}_{-26} \text{ GeV}$$

- Direct and model-independent search at LEP up to 209 GeV cms gave a 95% CL lower bound on m_H

$$m_H > 114.4 \text{ GeV } 95\% \text{ CL}$$

- Direct search after LEP shutdown in 2000 at Tevatron ppbar collider using 10fb-1 gave

a] excluded intervals 90-109 GeV and 149-182 GeV

b] broad excess at the level of 3σ in the interval $115 < m_H < 140$ GeV with a maximum at 125 GeV

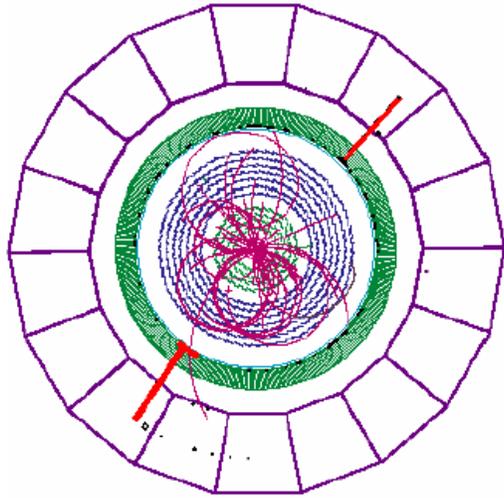

- LHC run in 2011 (7 TeV, 5 fb⁻¹), 2012 (8 TeV, 20 fb⁻¹) gave evidence for a new particle decaying to $\gamma\gamma$ and ZZ with rates as predicted by SM. Evidence for decays to W^+W^- but no evidence for $b\bar{b}$ and $\tau^+\tau^-$
- LHC July 2012 : ATLAS & CMS claim a discovery of a new particle with a mass of about 125 GeV

Most Promising Higgs Decay Channels

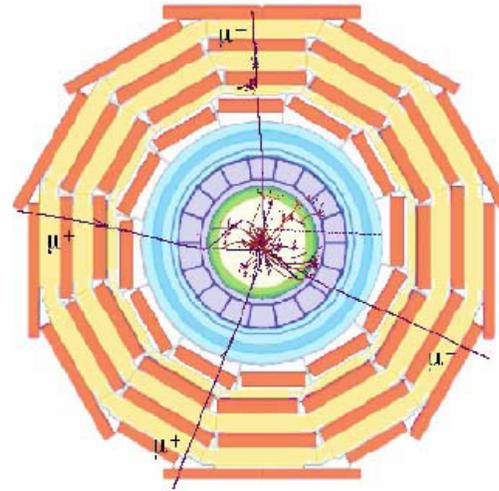

| Channel | LHC Potential |
|---|---|
| $gg \rightarrow H \rightarrow bb$ | Huge QCD background ($gg \rightarrow bb$); extremely difficult |
| $gg \rightarrow H \rightarrow \tau\tau$ | Higgs with low p_T , hard to discriminate from background; problematic |
| $gg \rightarrow H \rightarrow \gamma\gamma$ | Small rate, large combinatorial background, but excellent determination of m_H (CMS: crystal calorimeter) |
| $gg \rightarrow H \rightarrow WW$ | Large rate, but 2 neutrinos in leptonic decay, Higgs spin accessible via lepton angular correlations |
| $gg \rightarrow H \rightarrow ZZ$ | $ZZ \rightarrow 4\mu$: "gold-plated" channel for high-mass Higgs (ATLAS: muon spectrometer) |

production
modes

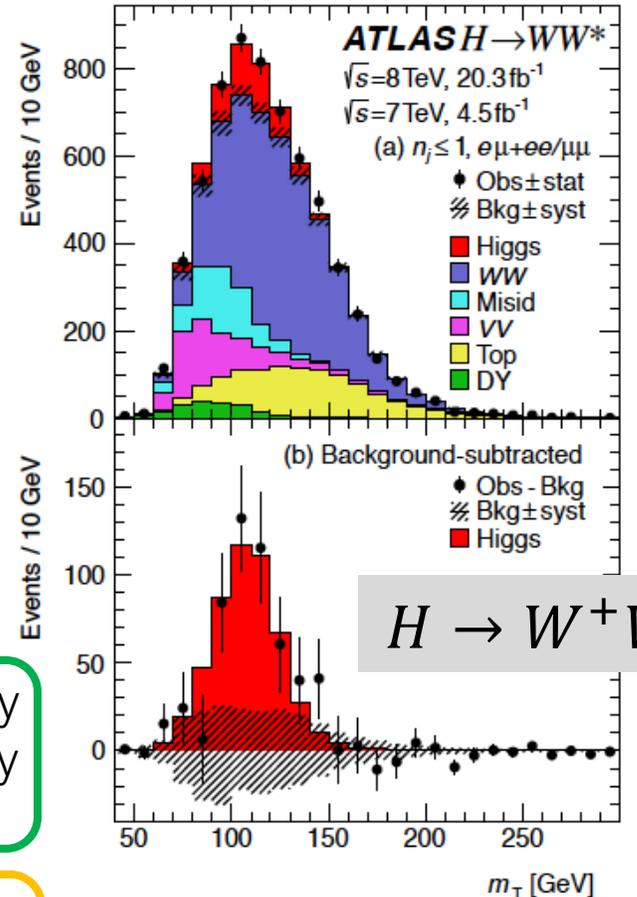

Summary of LHC Run-1 Results (7 TeV + 8 TeV)

$H \rightarrow \gamma\gamma$

$H \rightarrow ZZ \rightarrow 4l$

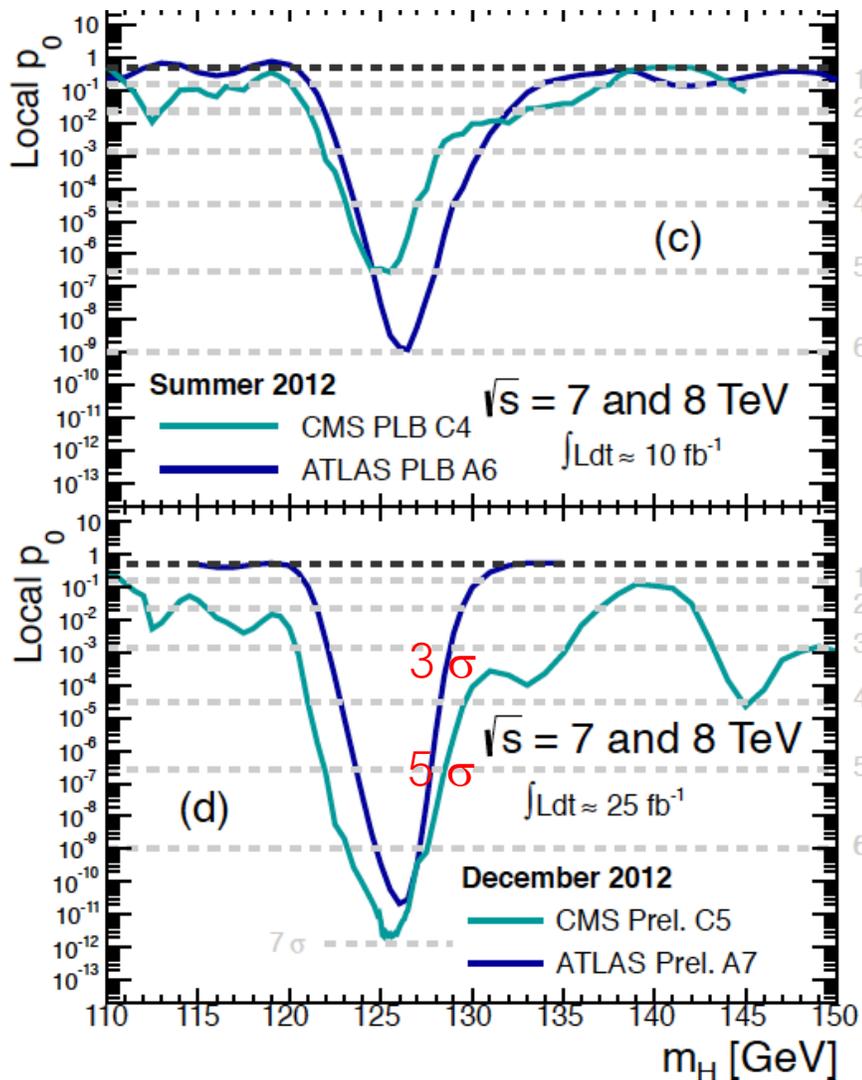

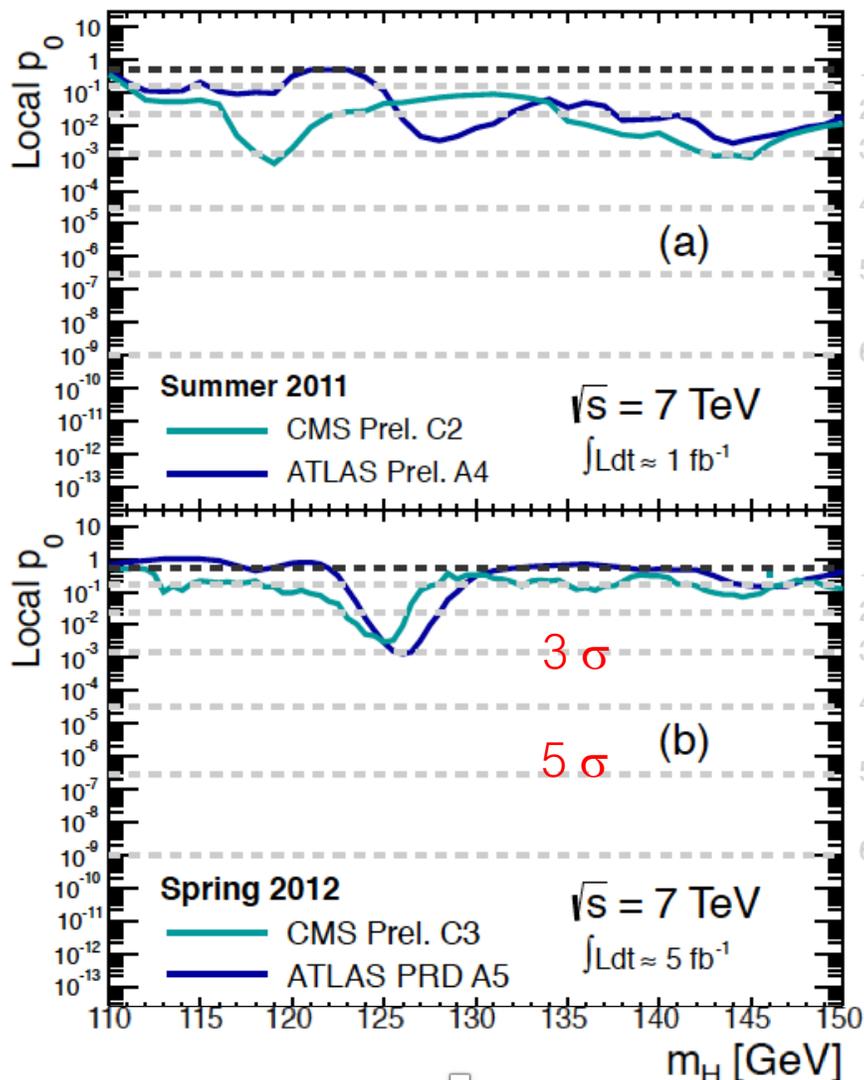

$H \rightarrow W^+W^-$

- In the $H \rightarrow \gamma\gamma$ and $H \rightarrow ZZ \rightarrow 4l$ channels, all final state particles can be very precisely measured and the reconstructed m_H resolution is excellent (typically 1-2%).

- the $H \rightarrow W^+W^- \rightarrow l^+\nu_l l^-\bar{\nu}_l$ channel has relatively large branching fraction, but the m_H resolution is poor (approximately 20%) due to the presence of neutrinos.

The Discovery

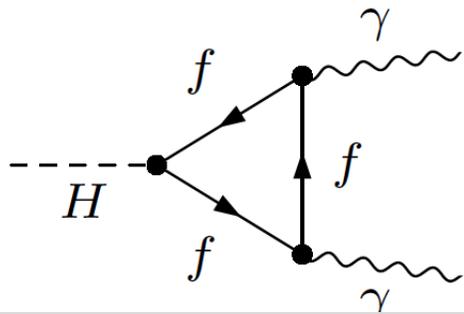

p_0 = probability that the excess can be described by background only

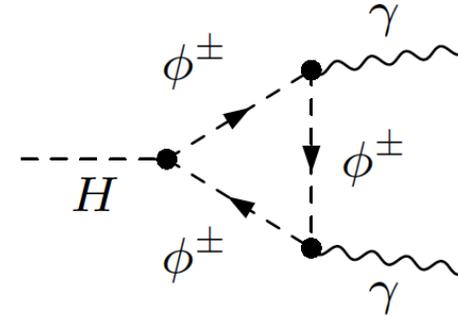

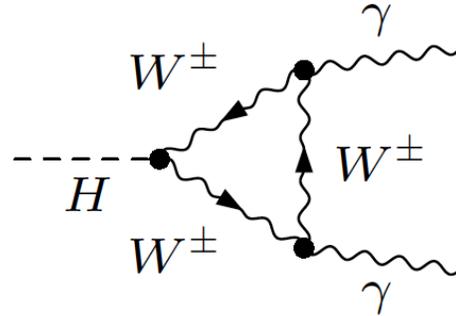

- *integrate all production modes for one decay channel*
- *Decays rates to $\gamma\gamma$ and ZZ consistent with (SM) Higgs boson.*
- There were indications that the new particle also decays to W^+W^- .

A p_0 of 2.87×10^{-7} corresponds to 5σ excess over the background-only prediction.

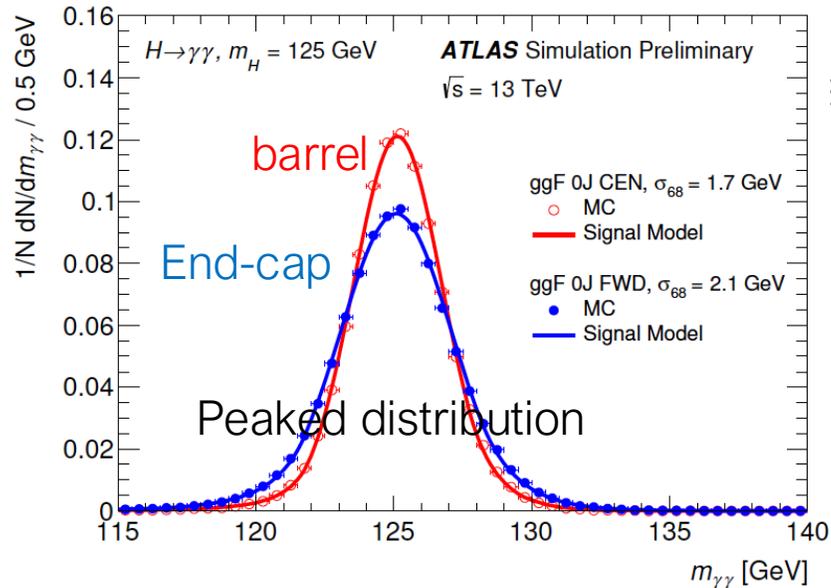

Higgs Decay to Two Photons

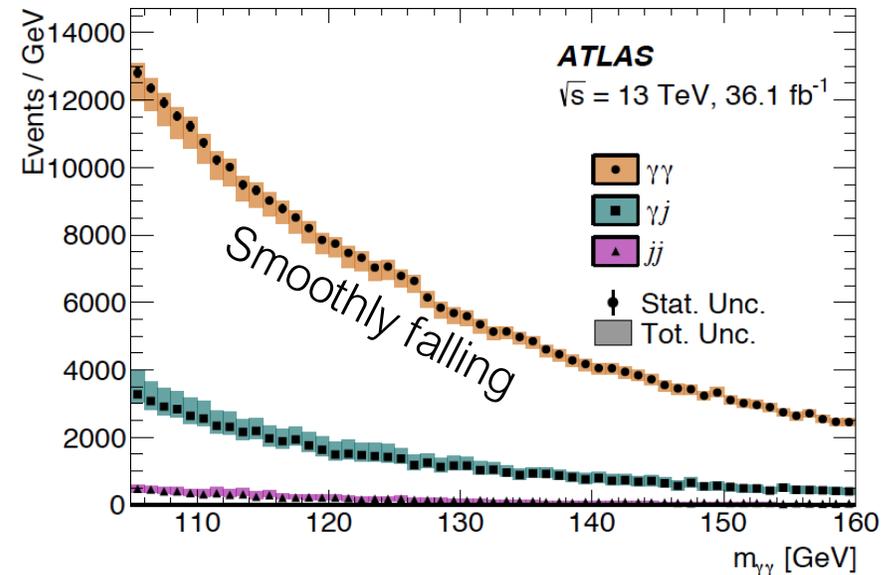

~Only top quarks contribute, contributions from light fermions negligible

Method: look for a peak in the invariant mass of two high p_T photons over a smoothly falling background distribution.

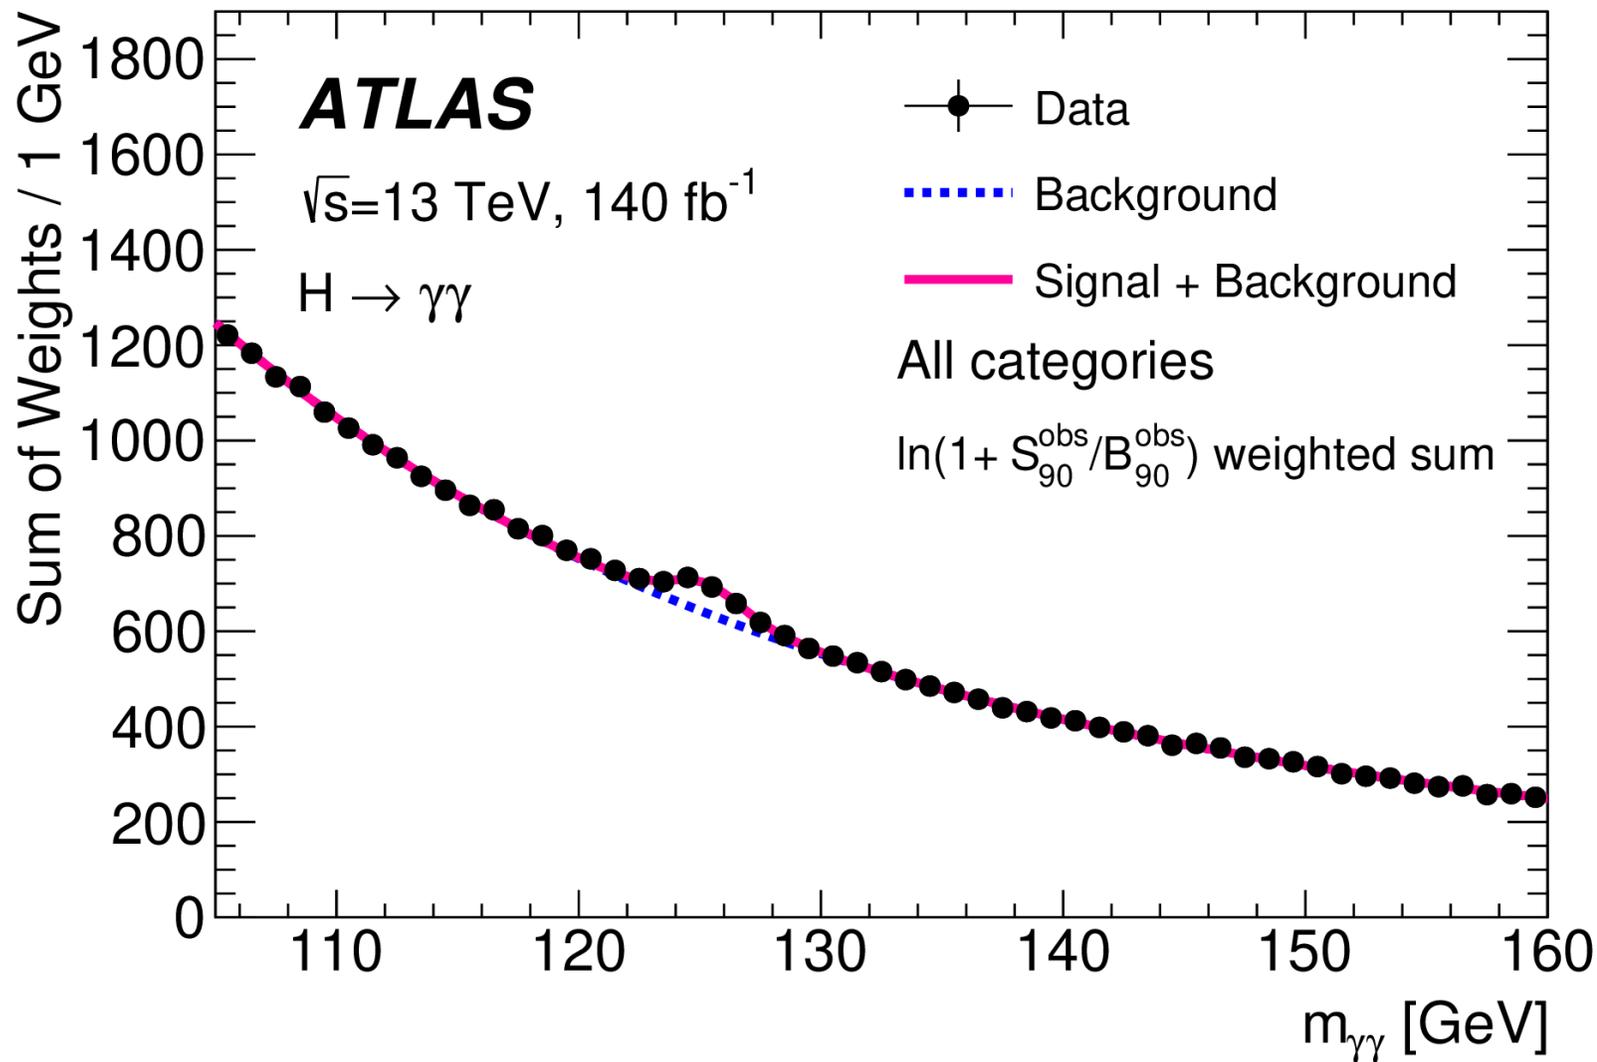

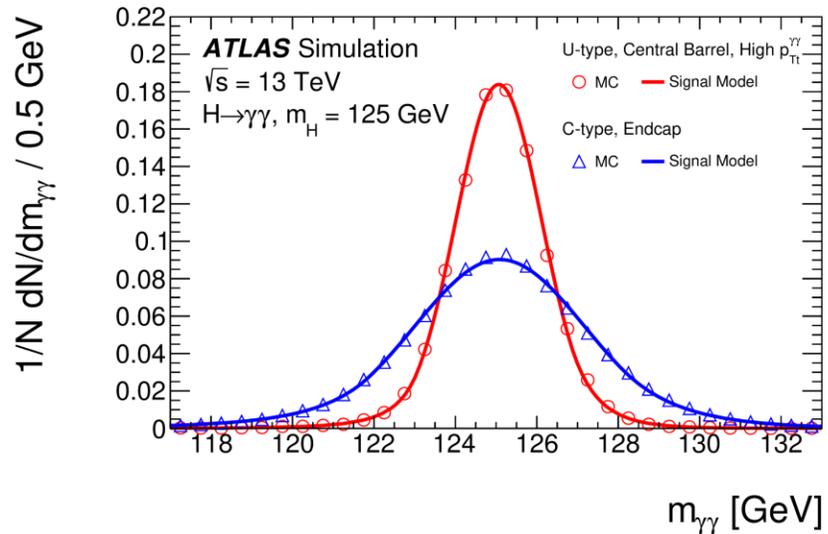

Gaussian central part + power law tails on both sides.

Fits to large control samples of data or simulated background events

More Recent Data $H \rightarrow \gamma\gamma$

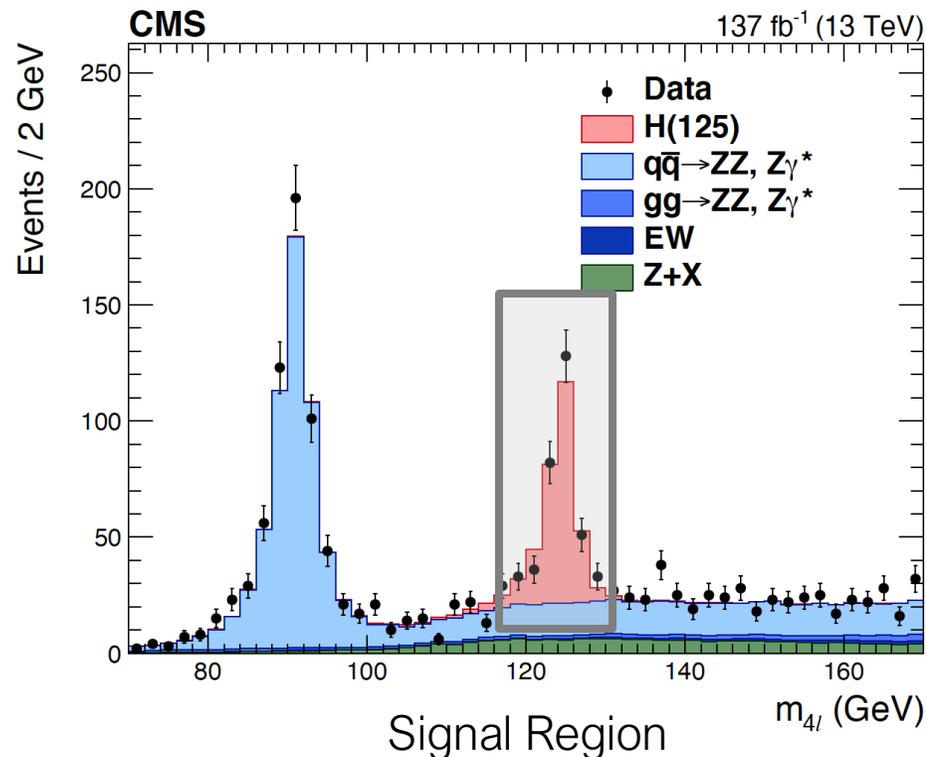

Higgs decay to $ZZ \rightarrow 4 \text{ leptons}$ (80 fb^{-1})

Method: $H \rightarrow ZZ^* \rightarrow l^+ l^- l'^+ l'^-$ look for a narrow mass peak over a continuous background.

$$H \rightarrow ZZ^* \rightarrow 4\ell \text{ decay } (4\mu, 2e2\mu, 2\mu2e, 4e)$$

Different event-observables \rightarrow the probability for the event to be signal-like or background-like
Event selection to magnify the ratio S/B

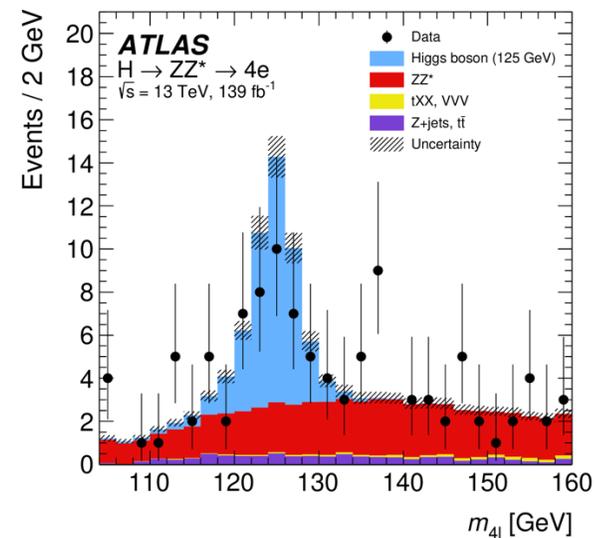

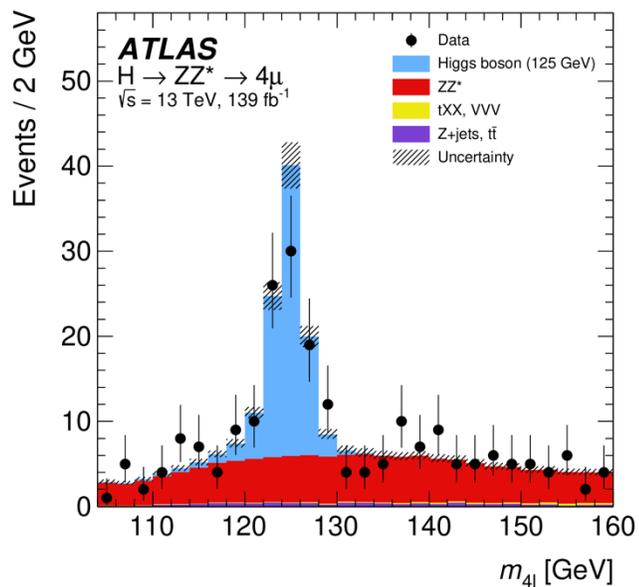

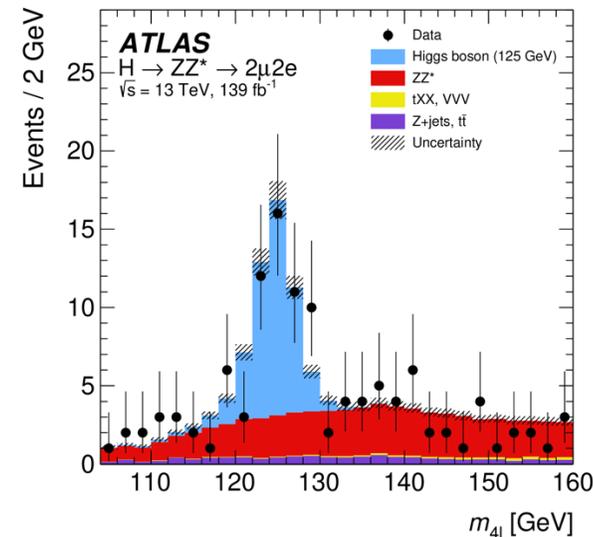

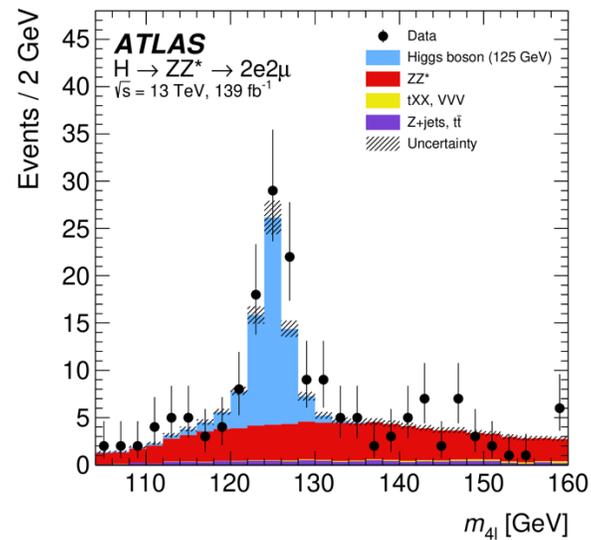

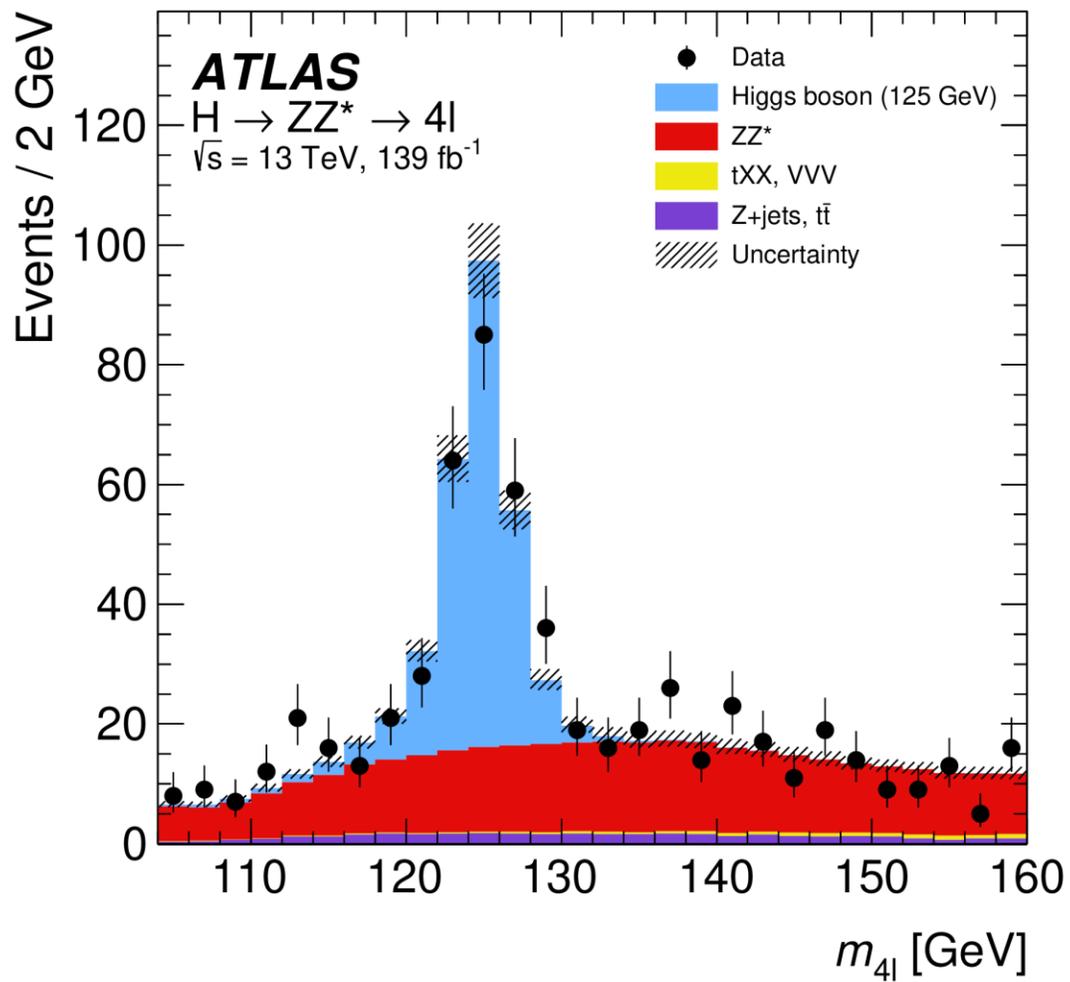

Number of expected and observed events in the four decay channels after the event selection, in the mass range $115 \text{ GeV} < m_{4l} < 130 \text{ GeV}$.

The sum of the expected number of SM Higgs boson events and the estimated background yields is compared to the data.

| Final state | Signal | ZZ^* background | Other backgrounds | Total expected | Observed |
|--------------|-------------------------------|------------------------------|-----------------------------------|-------------------------------|------------|
| 4μ | 40.5 ± 1.7 | 19.0 ± 1.1 | 1.71 ± 0.10 | 61.2 ± 2.0 | 64 |
| $2e2\mu$ | 28.2 ± 1.2 | 13.3 ± 0.8 | 1.38 ± 0.10 | 42.8 ± 1.4 | 64 |
| $2\mu2e$ | 22.1 ± 1.4 | 9.2 ± 0.9 | 2.99 ± 0.09 | 34.3 ± 1.7 | 39 |
| $4e$ | 21.1 ± 1.4 | 8.6 ± 0.8 | 2.90 ± 0.09 | 32.5 ± 1.6 | 28 |
| Total | 112 ± 5 | 50 ± 4 | 8.96 ± 0.12 | 171 ± 6 | 195 |

Agreement data/MC to 1.7σ

More Recent Data $H \rightarrow ZZ \rightarrow 4l$

Topologies of Production Mechanisms

ggf, gluon-fusion process :

- largest cross section
- Loop with heavy top quark. *No very distinctive feature in the topology!*

VBF, vector boson fusion :

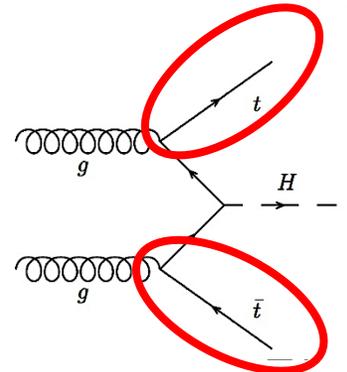

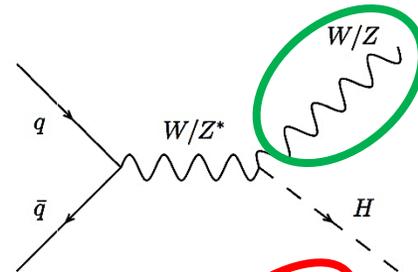

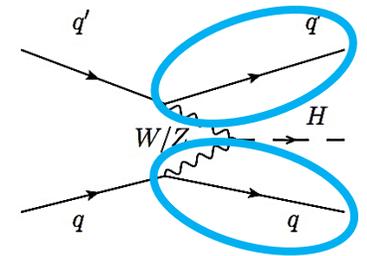

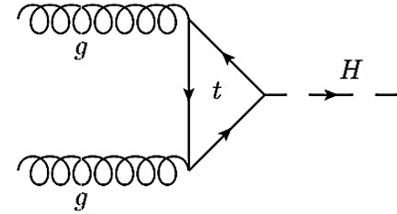

- second-largest cross section
- scattering of qq' ($q\bar{q}$), mediated by the exchange of a W or Z boson.
- The scattered quarks give two hard jets in the forward and backward regions with a large dijet mass ($\geq 400\text{GeV}$) and separated by $\Delta\eta_{jj} \geq 3.5 \rightarrow$ one jet very forward + 1 jet very backward.

VH, associated production with W and Z gauge bosons :

- Third cross-section
- W and Z leptonic decay(s) \rightarrow MET & high p_T leptons \rightarrow clean signatures.

ttH: Higgs radiation off top quarks

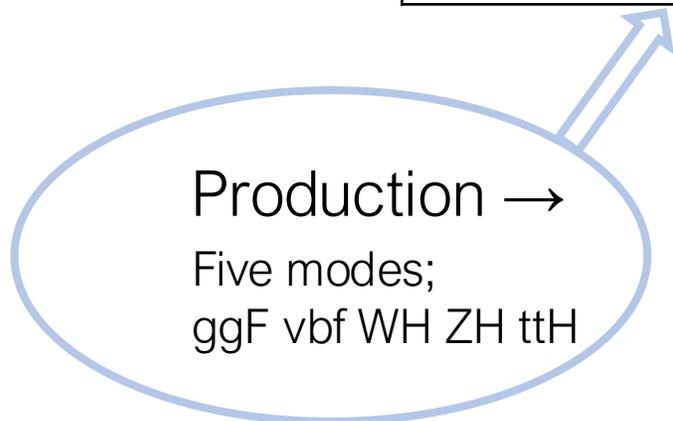

- High p_T leptons, MET, b-tagged jets. Complex topology with many decay channels

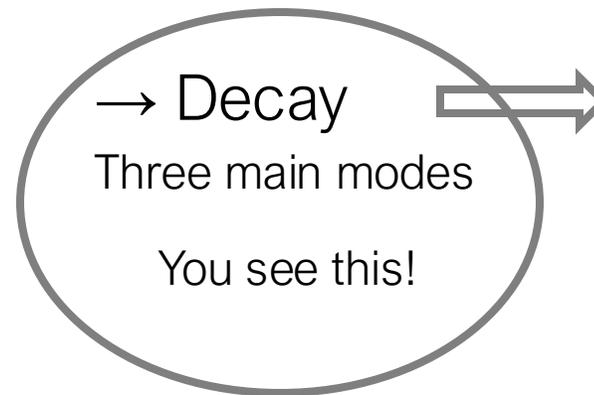

Improve Initial Discovery

Is the observed resonance the Higgs boson predicted by the SM?
→ more analysis

| Higgses produced in ATLAS & CMS in LHC Run 1 | | | | |
|--|---------|--------|--------|-------|
| Production Mode | ggF | VBF | WH+ZH | ttH |
| Higgs events | 500.000 | 40.000 | 20.000 | 3.000 |

Higgs

There are three main decay channels: the $\gamma\gamma$, ZZ, WW

$3 \times 5 = 15$ combinations → too many for an (initial) search, not enough statistics!

Events selected for the discovery were very few: between 1 and 100 for each production-decay category.

Of the Categorisation

Initial discovery was based on a low sample of events → limited sensitivity to SM Higgs predictions

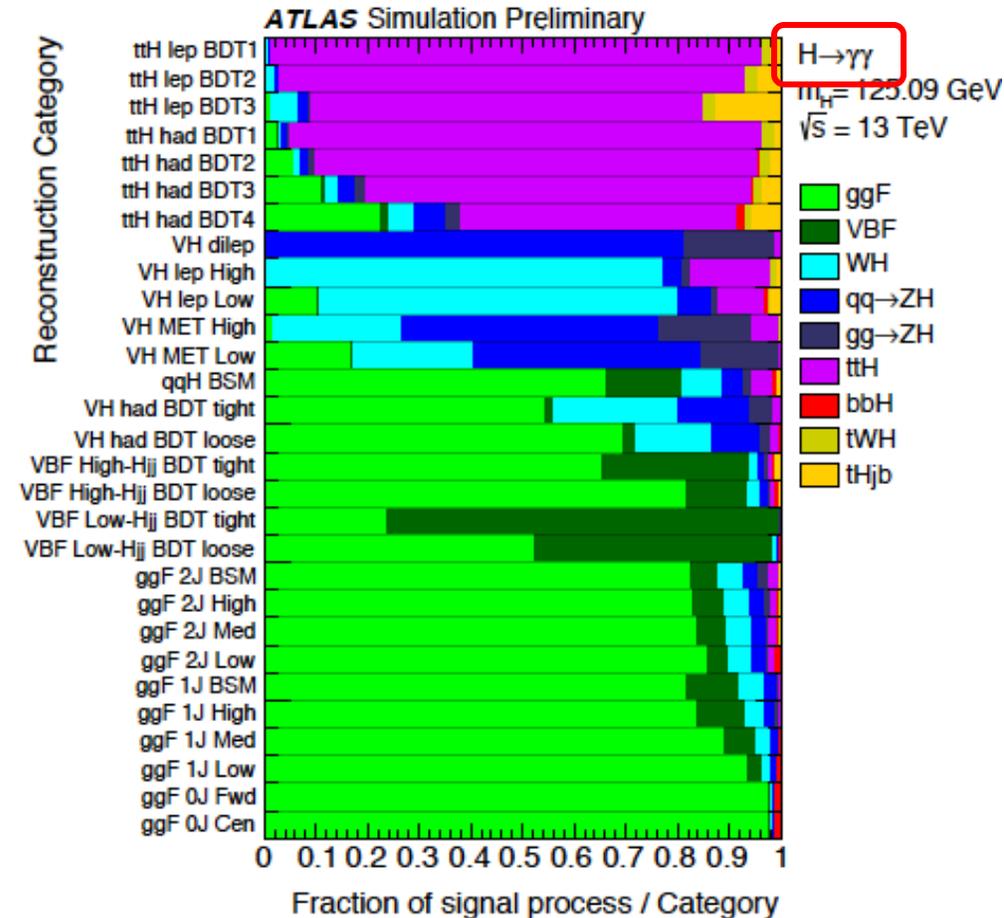

- Selection: **decay modes only**, integrate production modes
- **Peak in the mass → a resonance, not necessarily a Higgs**
- Later in time → more statistics → Need to check if also production modes are in agreement with SM

Start with most distinctive and finish with least distinctive

decision

- Separate production processes with topological characteristics → categorisation.
- One category ~ mostly one production mode (but also contamination from others) → not a measurement of that production cross-section.
- Simulations are used to determine the relative contributions of the various Higgs production modes in a particular category.

Categorisation of $H \rightarrow \gamma\gamma$

Example: $H \rightarrow \gamma\gamma$

Several production modes:

1. Consider one production mode at a time (from the most distinct, ttH , to the least distinct, ggf)
2. Is the topology / kinematics of that event compatible with that production?

No

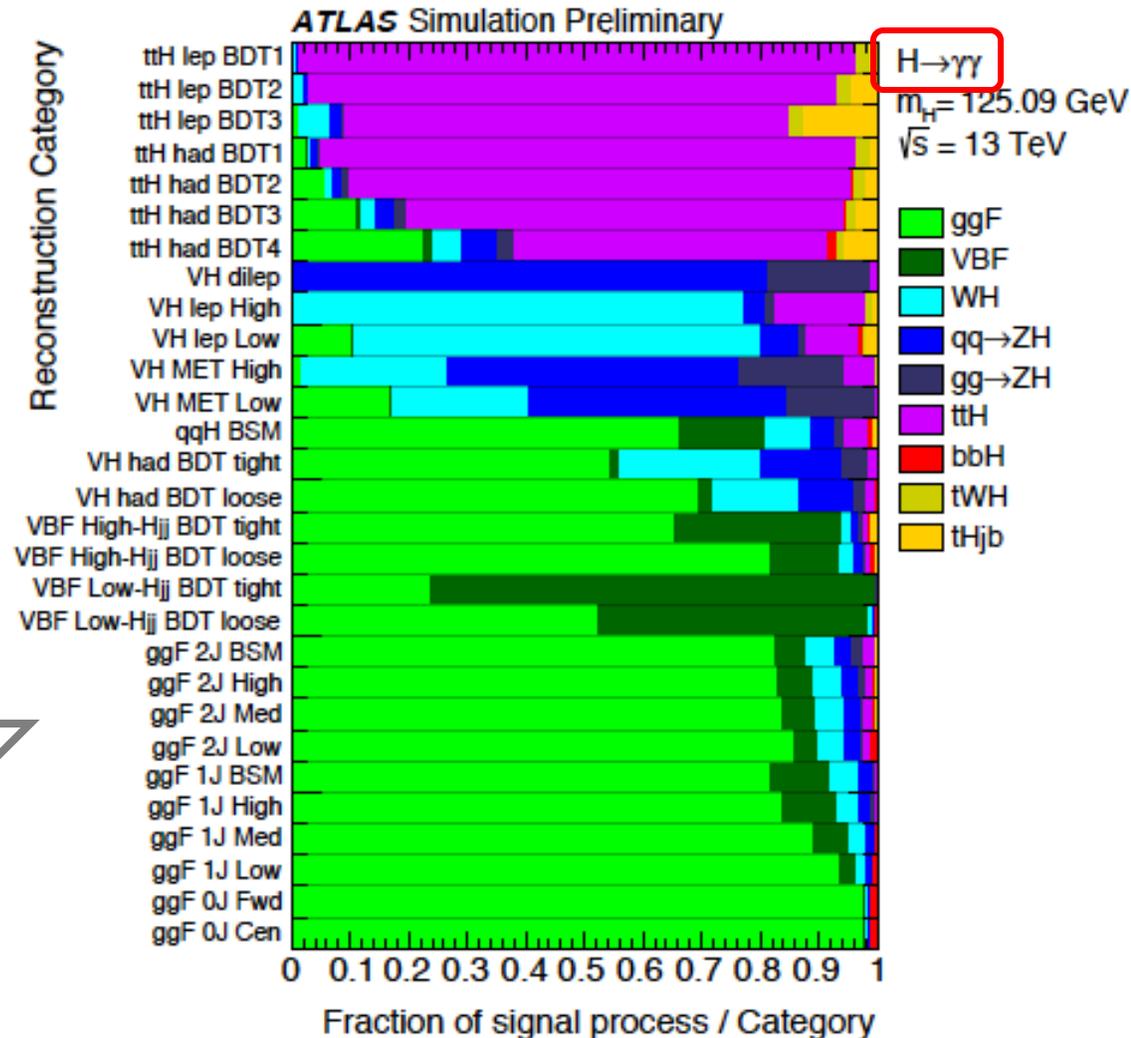

Go to next production

Yes

Go to next event

- Attribution to one category is exclusive!
- There is some wrong attribution
- Composition of one category studied by MC

decision

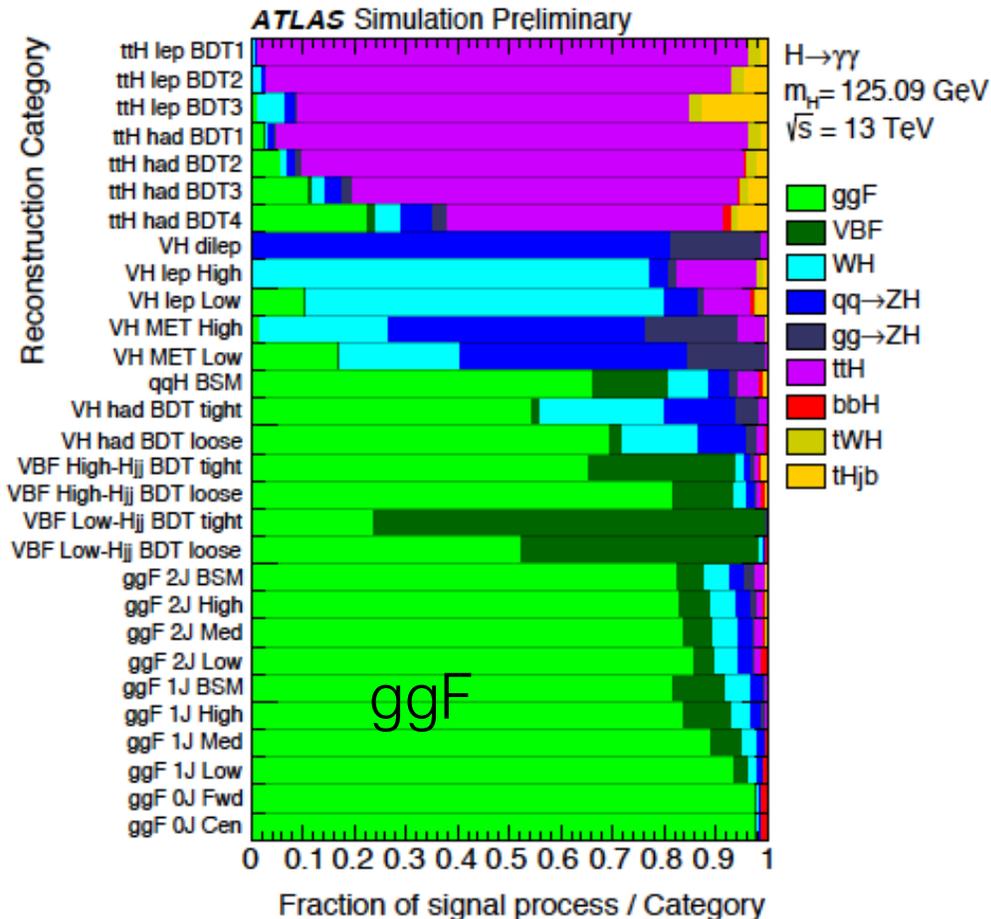

29 Categories in Higgs $\rightarrow \gamma\gamma$

Summary of the 29 event reconstruction categories for the measurement of production mode cross sections.

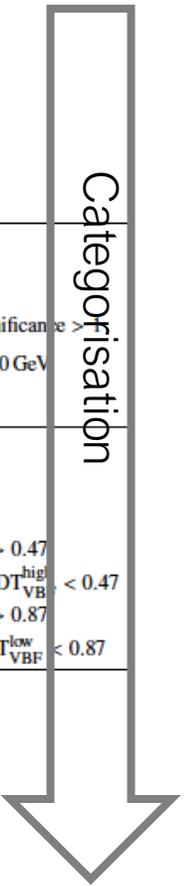

Each event is assigned to the first category whose requirements are satisfied, using the descending order given in the table.

As a result, the event populations of categories are mutually exclusive.

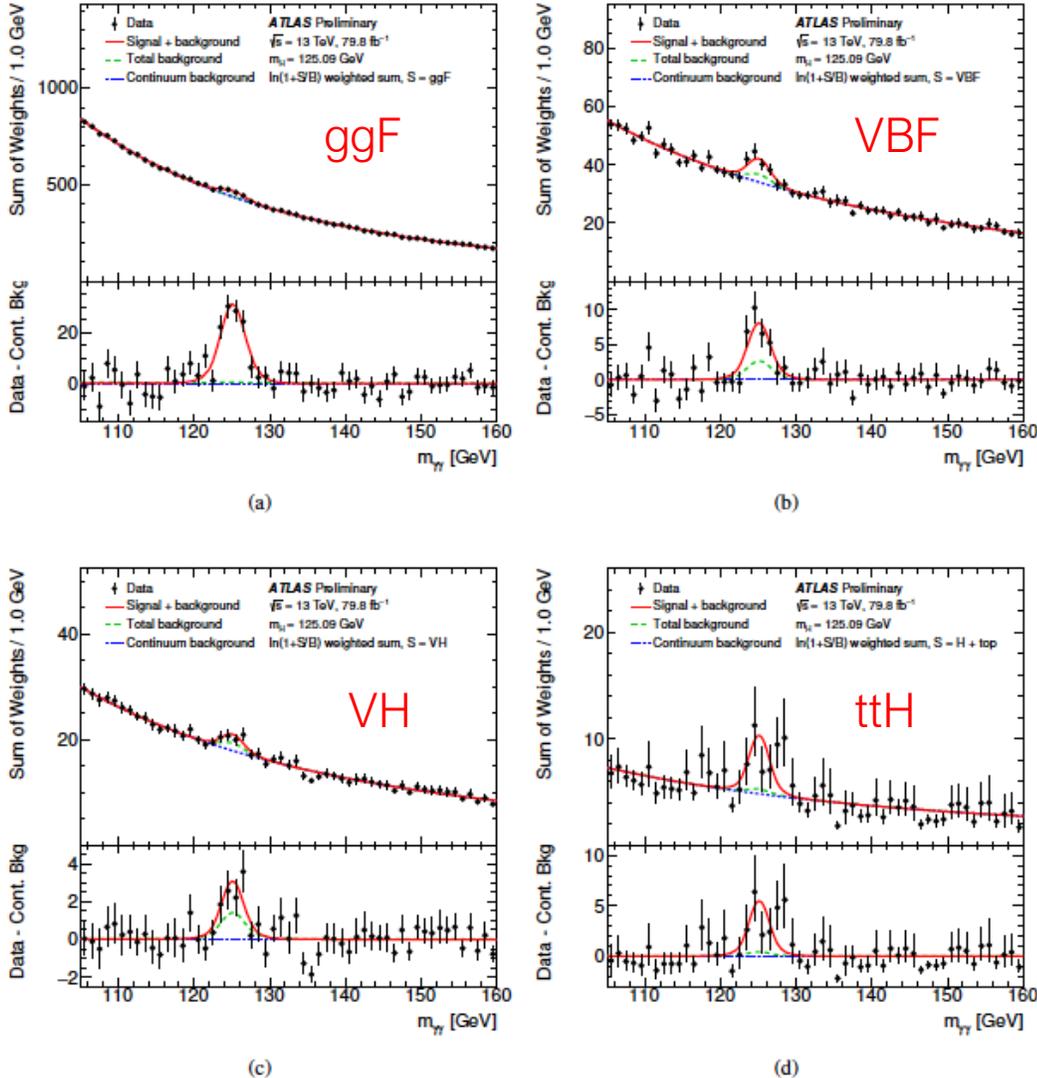

| Category label | Selection |
|---------------------------------|--|
| ttH lep BDT1 | $N_{lep} \geq 1, N_{b-jet} \geq 1, BDT_{ttHlep} > 0.987$ |

Categorisation

The $m_{\gamma\gamma}$ distribution with $\sim 80\text{fb}^{-1}$

$m_{\gamma\gamma}$ in the four production categories

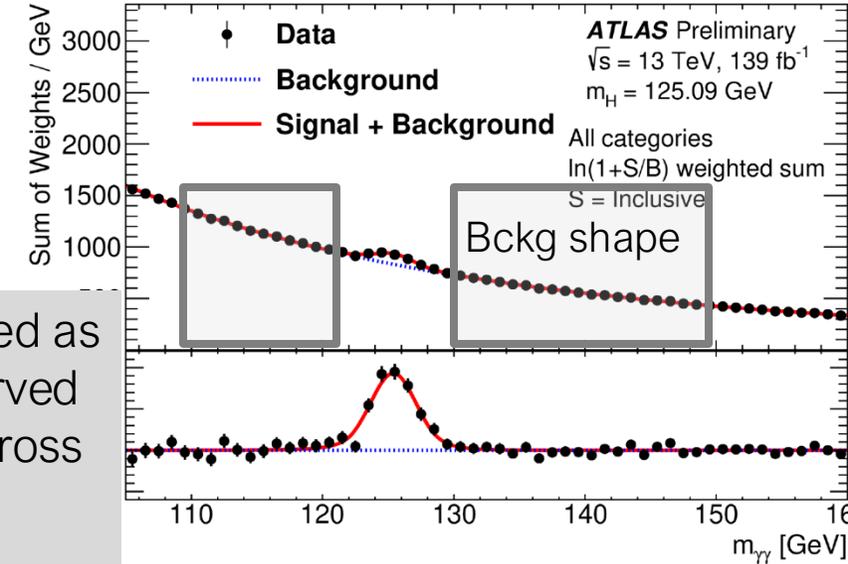

Cumulated $m_{\gamma\gamma}$ distribution for the H $\rightarrow \gamma\gamma$ decay

Signal-strength is defined as the ratio between observed and the SM expected cross section

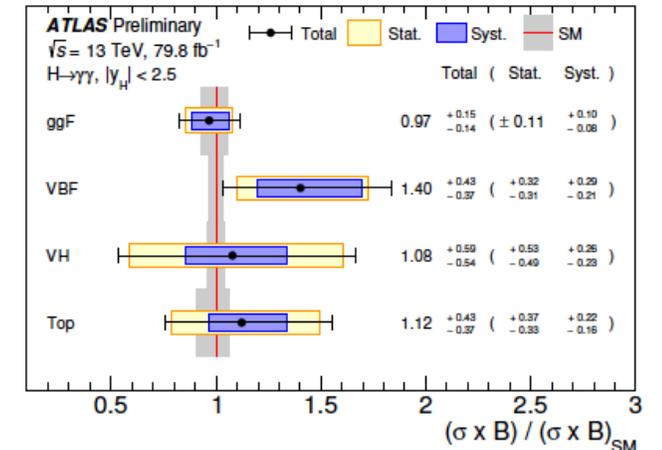

$$\mu = \frac{\sigma^{\text{measured}} \times BR^{\text{measured}}}{\sigma^{\text{SM}} \times BR^{\text{SM}}}$$

This observable tells how well data are in agreement with SM

Signal consists of between 150 and 200 $H \rightarrow \gamma\gamma$ decay candidates

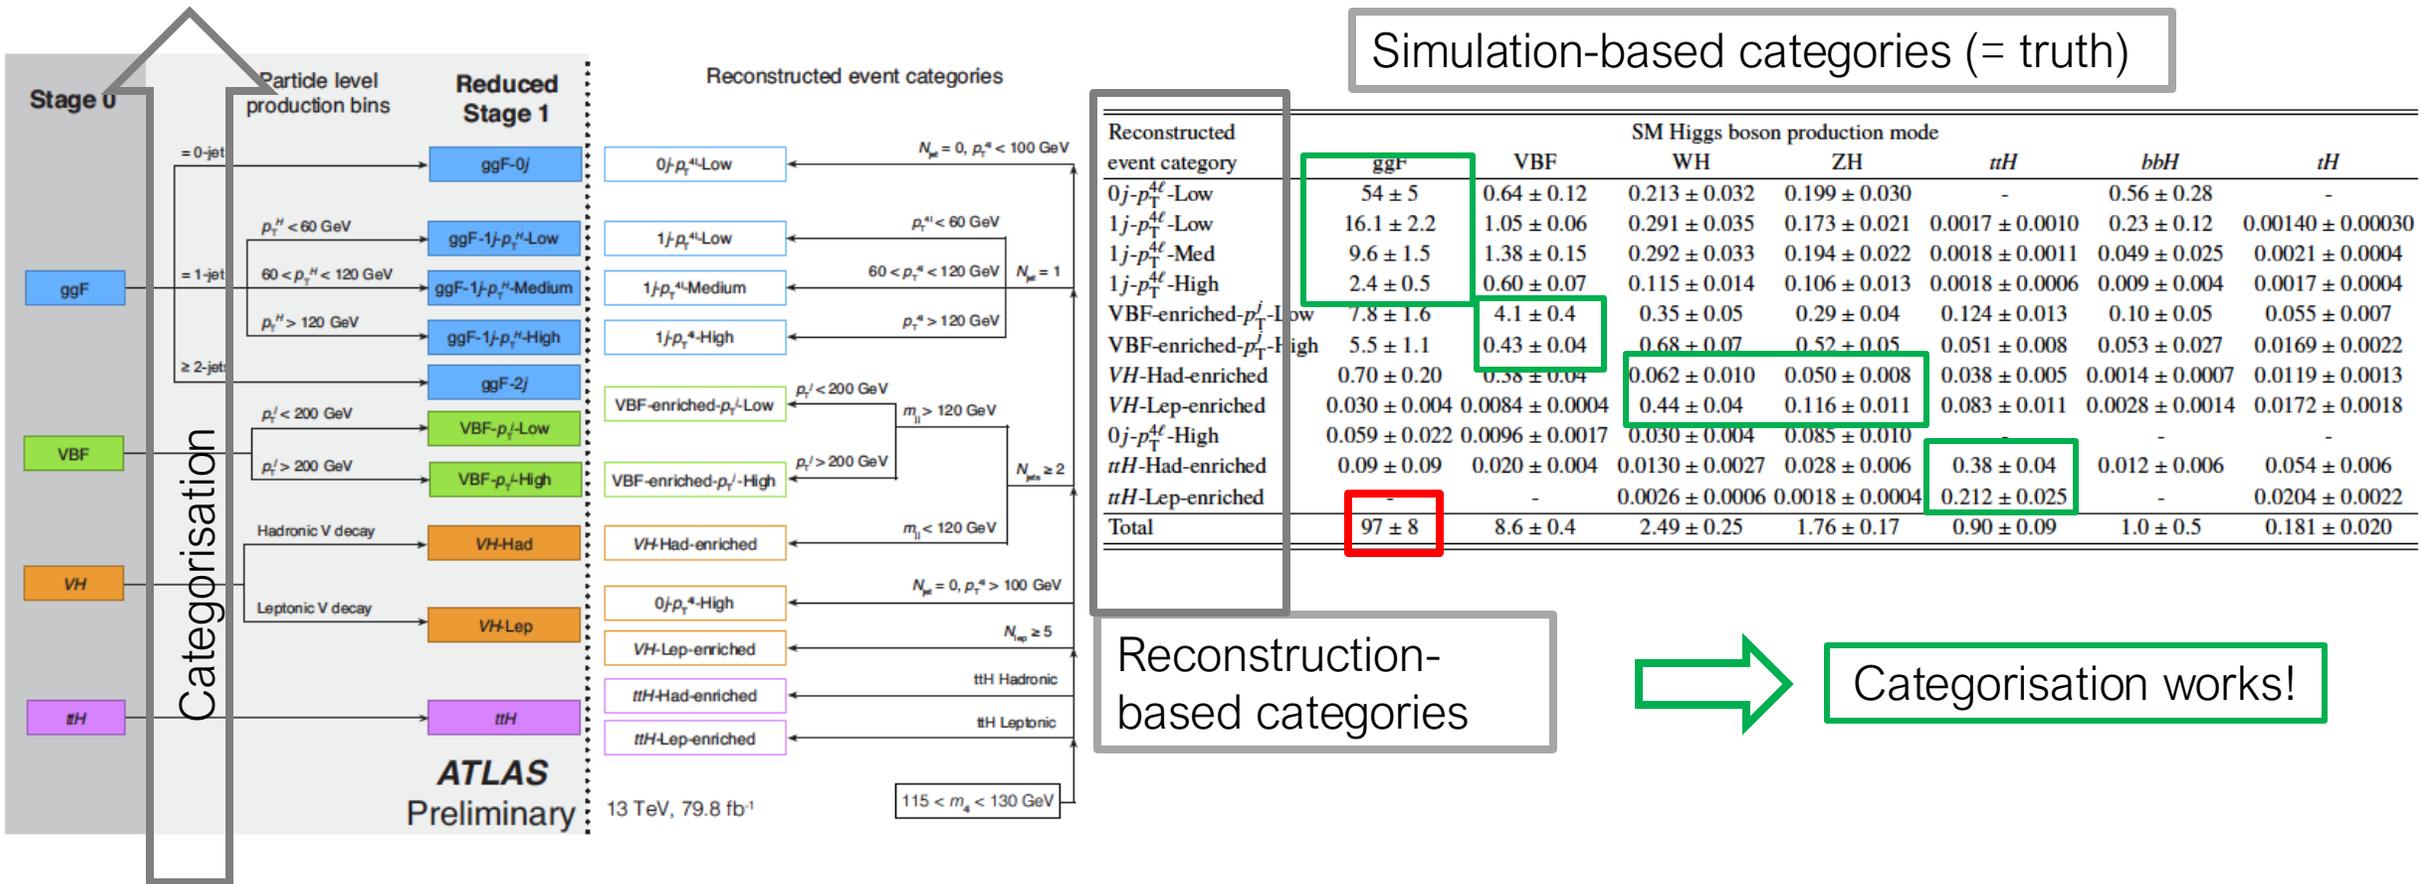

μ for the H $\rightarrow \gamma\gamma$ decay channel

Composition of the Signal $H \rightarrow ZZ \rightarrow 4\ell$

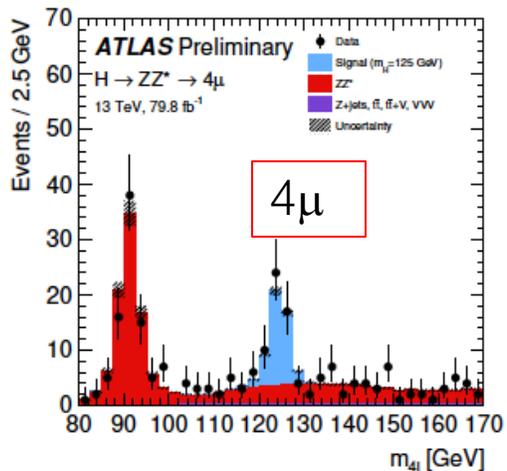

A categorisation ~similar to what was used for the $H \rightarrow \gamma\gamma$ decay is also used for the $H \rightarrow 4\ell$ decay

Simulated signal composition for ~80 fb⁻¹ of luminosity at 13 TeV: The **ggF** component, as expected, dominates.

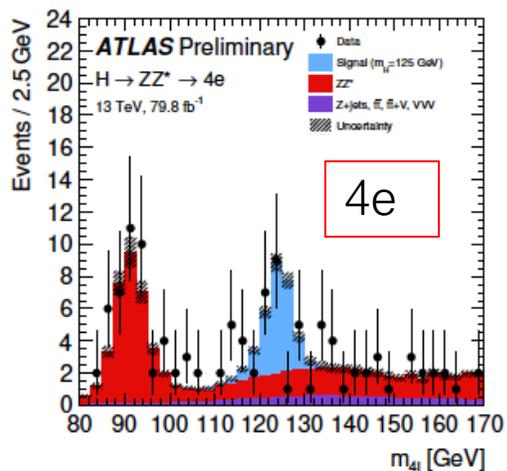

A correspondence is determined between reconstruction and simulation categories

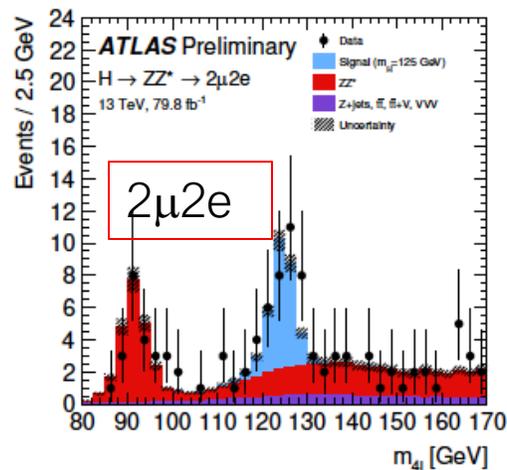

Details of the Results

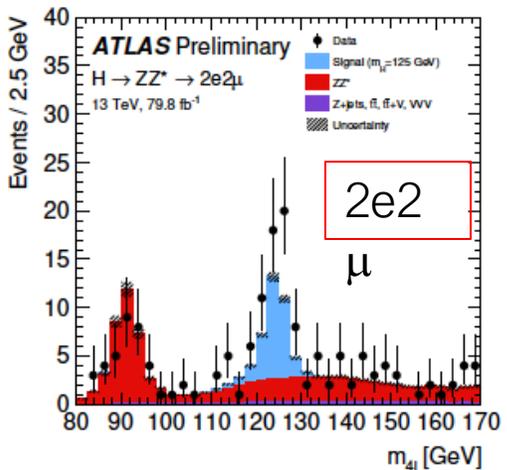

(a)

(b)

(c)

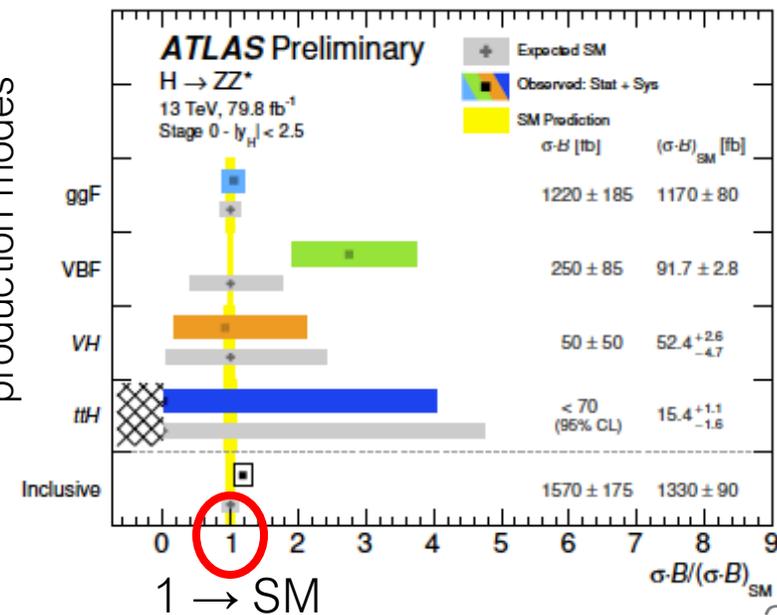

(d)

| Cross section [fb] | Data (\pm (stat.) \pm (syst.)) | Standard Model prediction | p -value [%] |
|--------------------|--------------------------------------|---------------------------|----------------|
| $\sigma_{4\mu}$ | $0.97 \pm 0.17 \pm 0.05$ | 0.886 ± 0.039 | 62 |
| σ_{4e} | $0.61 \pm 0.21 \pm 0.07$ | 0.886 ± 0.039 | 25 |
| $\sigma_{2\mu 2e}$ | $0.88 \pm 0.21 \pm 0.08$ | 0.786 ± 0.035 | 66 |
| $\sigma_{2e 2\mu}$ | $1.37 \pm 0.22 \pm 0.07$ | 0.786 ± 0.035 | 0.3 |

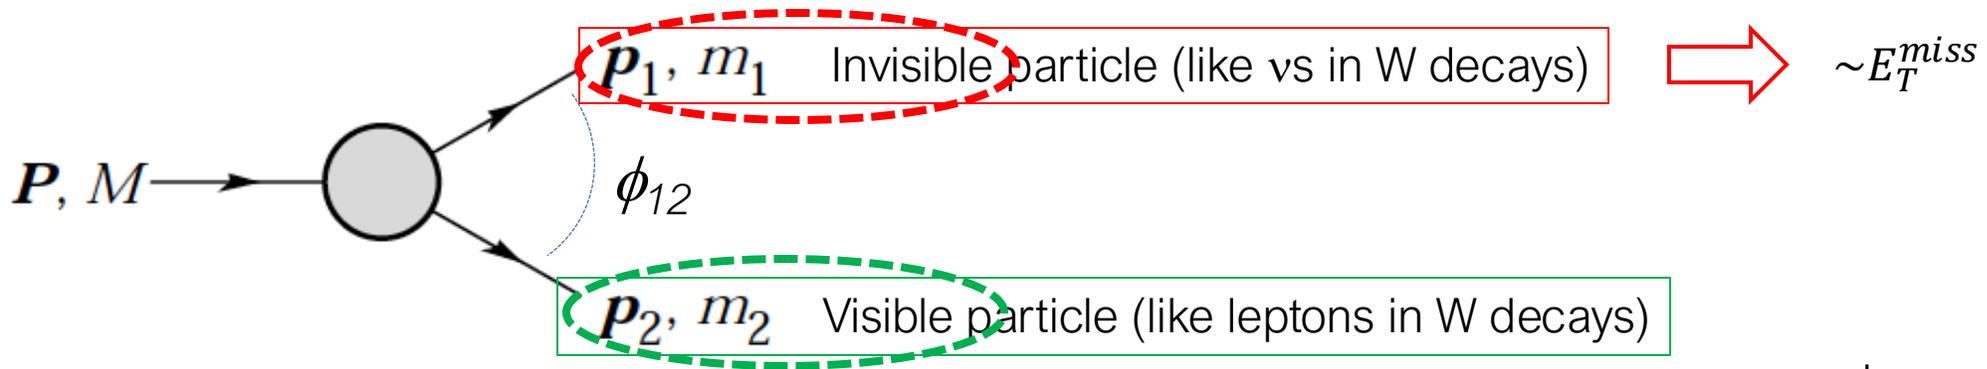

The signal strength μ has also been calculated:

Integrated $\mu = 1.19 \pm 0.12(\text{stat.}) \pm 0.06(\text{exp.})^{+0.08}_{-0.07}(\text{th.}) = 1.19^{+0.16}_{-0.15}$

Signal strength for different production modes

W Mass Measurements at Hadron Colliders

The mass of the parent particle can be constrained with the observable M_T defined by

$$M_T^2 \equiv [E_T(1) + E_T(2)]^2 - [\mathbf{p}_T(1) + \mathbf{p}_T(2)]^2$$

$$= m_1^2 + m_2^2 + 2[E_T(1)E_T(2) - \mathbf{p}_T(1) \cdot \mathbf{p}_T(2)]$$

where

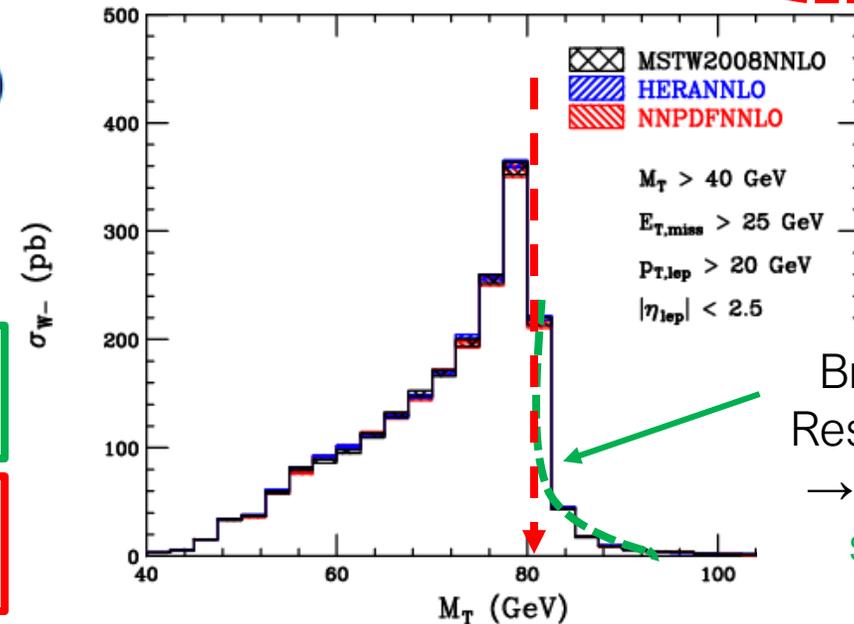

$$\mathbf{p}_T(1) = E_T^{miss}$$

For $m_1 \sim m_2 \sim 0 \rightarrow M_T^2 = 2|\mathbf{p}_T(1)||\mathbf{p}_T(2)|(1 - \cos \phi_{12})$

Important characteristic: the end point of this distribution is

$$M_T^{max} = M$$

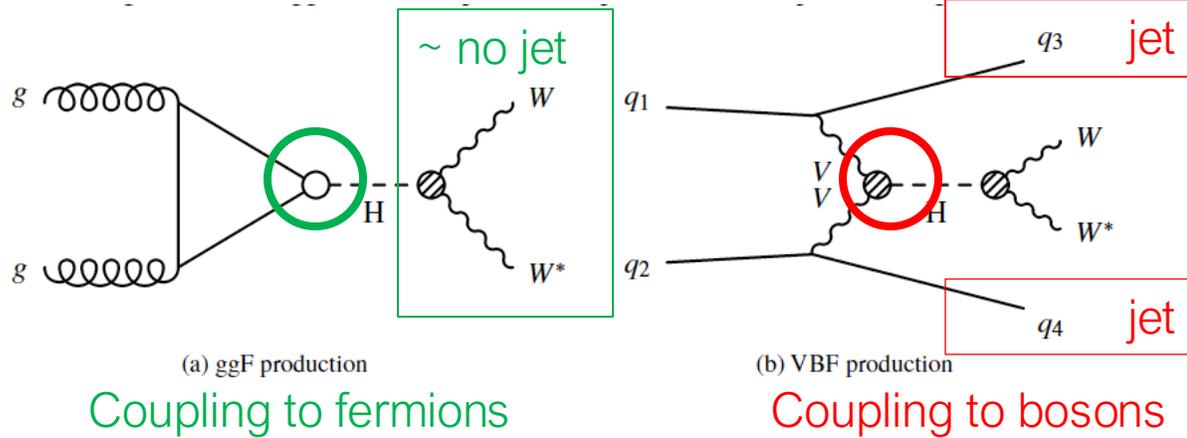

Also the distribution of the p_T of the lepton has memory of m_W : the end-point is $m_W/2$

Breit-Wigner+ Resolution effect
 \rightarrow sharp fall \rightarrow smooth fall

Higgs \rightarrow $WW \rightarrow e\nu \mu\nu$ (36 fb^{-1})

Signal strength (μ)

Correlation Between Production and Decay of the Higgs

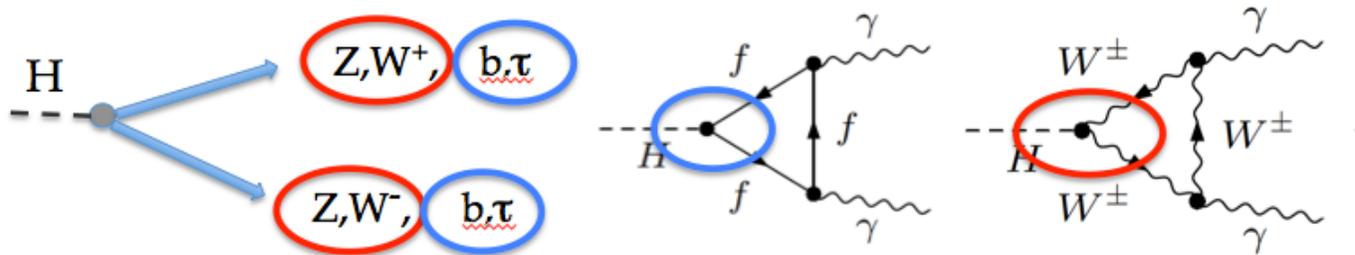

Same vertices in Higgs production and decay → in the SM they are dependent.

Use

$$\mu = \frac{\sigma^{measured} \times BR^{measured}}{\sigma^{SM} \times BR^{SM}}$$

→ if one vertex is modified by a correction factor **in production** the same correction factor has to modify also the corresponding vertex **in decay**

Use all possible measurements in the different categories and parametrise the correction factor with the signal strengths

One unique μ

The combination will give a better indication of how well SM describes data

The Analysis Model

$$n_s^c = \left(\sum_{i,f} \underbrace{\mu_i}_{\text{production}} \cdot \sigma_i^{SM} \cdot A_{if}^c \cdot \varepsilon_{if}^c \cdot \underbrace{\mu_f}_{\text{decay}} \cdot BR_f^{SM} \right) \cdot \mathcal{L}^c$$

n_s^c = number of events selected in one category c
Category is a sample of events selected by analysis cuts

- μ_i, μ_f is the ratio between the observed cross section / Branching fraction and the one predicted by the SM
- The production index $i \in \{ggH, \text{VBF}, \text{VH}, \text{ttH}\}$ and the decay index $f \in \{\gamma\gamma, \text{WW}, \text{ZZ}, \text{bb}, \tau\tau\}$
- σ_i^{SM} and BR_f^{SM} production cross sections, decay branching fractions for a SM Higgs
- A_{if}^c and ε_{if}^c are the signal acceptance and the reconstruction efficiency for given production and decay mode i in the category c .
- \mathcal{L}^c is the integrated luminosity used for that specific category.

Combination = fit μ_i and $\mu_f \rightarrow$ best agreement between data and (modified) SM prediction in different categories.

Includes Signal Regions and Control Regions

There are different ways of combination \rightarrow different assumptions (\sim simplifications)

How Complex is the Fit?

Decay

$$n_S^c = \left(\sum_{i,f} \mu_i \cdot \sigma_i^{SM} \cdot A_{if}^c \cdot \varepsilon_{if}^c \cdot \mu_f \cdot BR_f^{SM} \right) \cdot \mathcal{L}^c$$

$i \in \{ggH, VBF, VH (ZZ \& WW), ttH\}$

$f \in \{\gamma\gamma, WW, ZZ, bb, \tau\tau\}$

5 values of i (VH=WH+WZ)

5 values of f

A=ATLAS, C=CMS

| | $\gamma\gamma$ | ZZ (4 ℓ) | WW ($l\nu l\nu$) | $\tau^+\tau^-$ | $b\bar{b}$ |
|-----------------------------|----------------|----------------|--------------------|----------------|------------|
| ggF (high p_T^H) | A | A | — | A | — |
| ggF (incl. or low p_T^H) | A-C | A-C | A-C | A-C | — |
| ggF 1-jet | — | C | A-C | C | — |
| VBF | A-C | A-C | A-C | A-C | C |
| WH (1- ℓ) | A-C | A | A-C | C | A-C |
| WH (two jets) | A-C | A-C | A-C | — | — |
| ZH (0- ℓ) | A-C | A | — | — | A-C |
| ZH (2- ℓ) | A-C | A | A-C | C | A-C |
| ZH (two jets) | A-C | A-C | A-C | — | — |
| ttH (1- ℓ) | A-C | — | A-C | A-C | A-C |
| ttH (2- ℓ) | — | — | A-C | A-C | A-C |
| ttH (hadronic) | A-C | — | — | — | A |

Possible ways of fitting:

1. ixf makes 25 free parameters
2. One reference process (characterised by σ_{ref} and BR_{ref}) + σ_f/σ_{ref} + BR_f/BR_{ref} ($\rightarrow 1 + 4 + 4$ parameters)
3. Further assumptions (see later)
4. Effective Lagrangian, introduce vertex modifiers

Signal Strength (μ)

| Production mechanism | ggF | VBF | WH/ZH | ttH |
|---------------------------------|--------|--------|---------|-------|
| Events produced at the LHC | 500 K | 40 K | 20 K | 3 K |
| Selected events | O(500) | O(500) | O(50) | |
| Events produced at the Tevatron | 10 K | | 2 K | |

For each decay channel “c” we define categories to maximise the sensitivity of the analysis to one particular production mode.

However a mixture of different mechanisms in one category is inevitable.
 → This implies the cross section of one category is not the cross section of only one production mechanism.

$$n_s^c = \left(\sum_{i,f} \mu_i \cdot \sigma_i^{SM} \cdot A_{if}^c \cdot \epsilon_{if}^c \cdot \mu_f \cdot BR_f^{SM} \right) \cdot \mathcal{L}^c$$

Where μ_c is ratio between measured & expected events in that category and

$$i = ggf, VBF, VH, ttH \quad \text{and} \quad f = gg, WW, ZZ, bb, tt$$

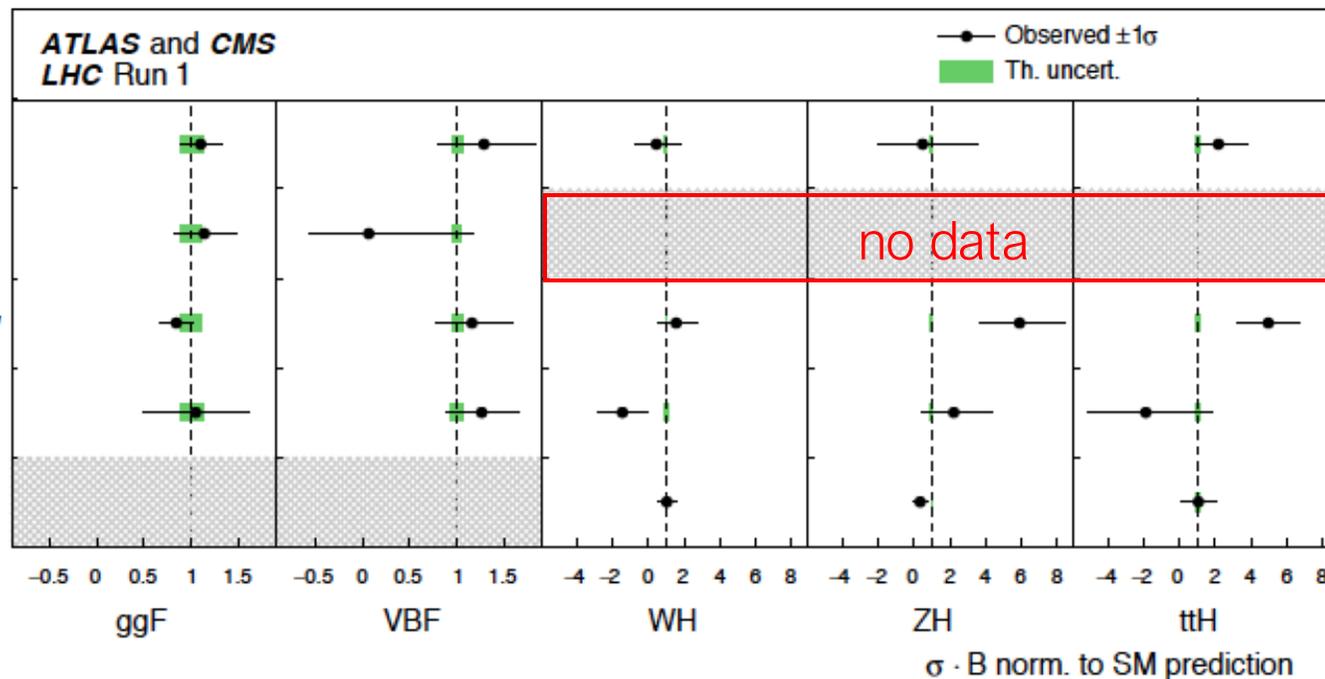

Measurement of μ_c gives an indication of how well SM describes data

Fit type 1 most general case

| | $\gamma\gamma$ | ZZ (4 ℓ) | WW ($l\nu l\nu$) | $\tau^+\tau^-$ | $b\bar{b}$ | Comb. |

| ZH | $0.5^{3.0}_{-2.5}^{+0.5}_{-0.2}$ | — | $5.9^{+2.3+1.1}_{-2.1-0.8}$ | $2.2^{+2.2+0.8}_{-1.7-0.6}$ | $0.4^{+0.3+0.2}_{-0.3-0.2}$ | $0.79^{+0.38}_{-0.36}$ |
| ttH | $2.2^{1.6}_{-1.3}^{+0.2}_{-0.1}$ | — | $5.0^{+1.5+1.0}_{-1.5-0.9}$ | $-1.9^{+3.2+1.9}_{-2.7-1.8}$ | $1.1^{+0.5+0.8}_{-0.5-0.8}$ | $2.3^{+0.7}_{-0.6}$ |
| Comb. | $1.14^{+0.19}_{-0.18}$ | $1.29^{+0.26}_{-0.23}$ | $1.09^{+0.18}_{-0.16}$ | $1.11^{+0.24}_{-0.22}$ | $0.70^{+0.29}_{-0.27}$ | $1.09^{+0.11}_{-0.10}$ |

$$\text{Signal Strength } \mu = \frac{(\sigma \cdot B)_{\text{obs}}}{(\sigma \cdot B)_{\text{SM}}}$$

- No significant deviation from the SM
- 25 – 5 = 20 parameters determined

Fit Type 2: Fewer Parameters

Take the Higgs produced via ggF and decaying to ZZ as reference

$i = \text{production}, f = \text{decay}$

$$\mu_i = \frac{\sigma_i}{\sigma_{ggF} \sigma_i^{SM}} \times \mu_{gg \rightarrow H \rightarrow ZZ}$$

$$\mu_f = \frac{BR_i}{BR_{ZZ} BR_i^{SM}}$$

$$\mu_{gg \rightarrow H \rightarrow ZZ} = \mu_{ggF} \times \mu_{ZZ} \times \sigma_i^{SM} \times BR_f^{SM}$$

Then, the master formula applies for all i and f indices except when

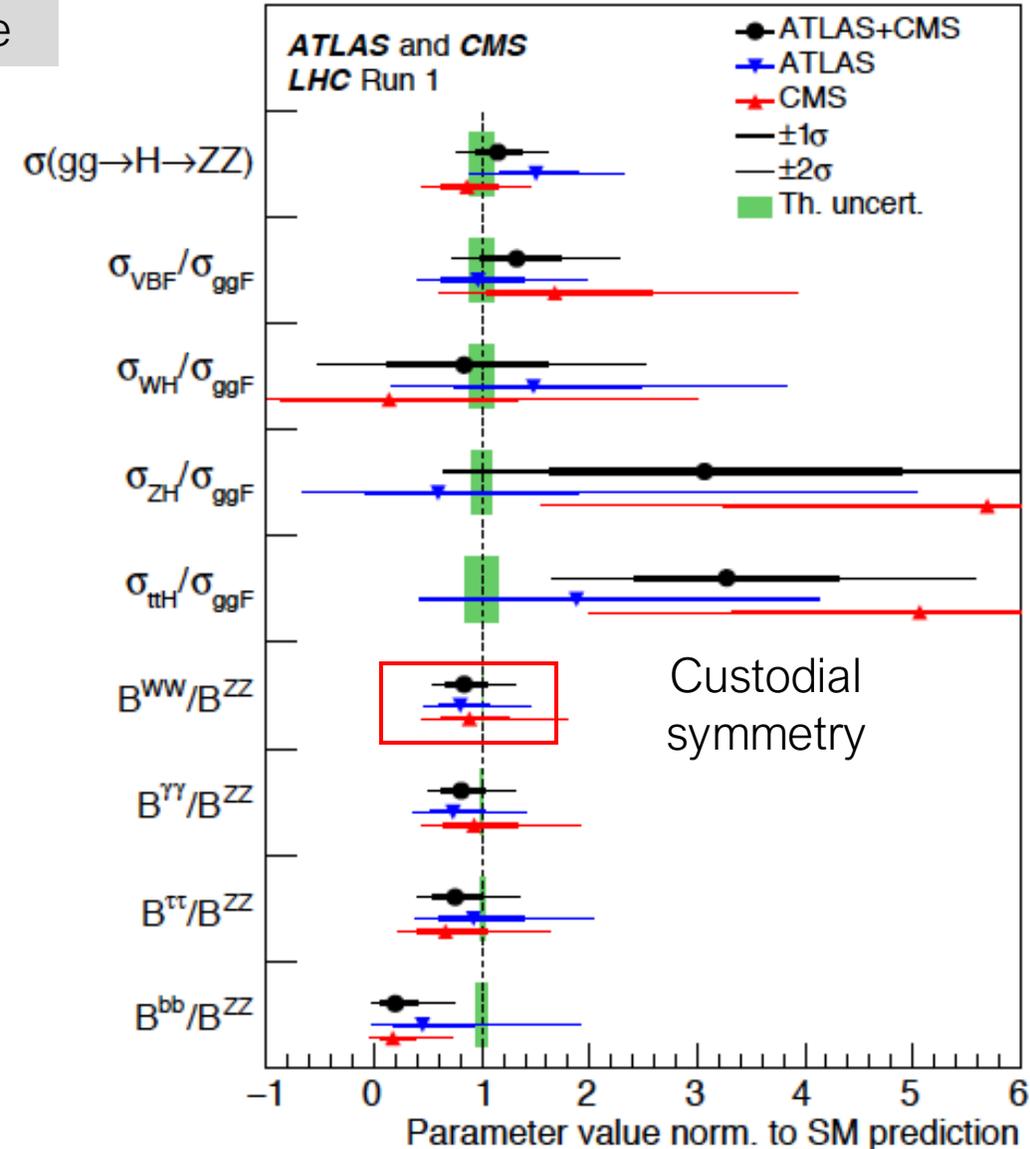

both $i = \text{ggF}$ and $f = \text{ZZ}$

$\rightarrow 8 + 1$ parameters

Improved precision in the fit, due to fewer parameters, shows no deviation from SM (assumption production and decay independent)

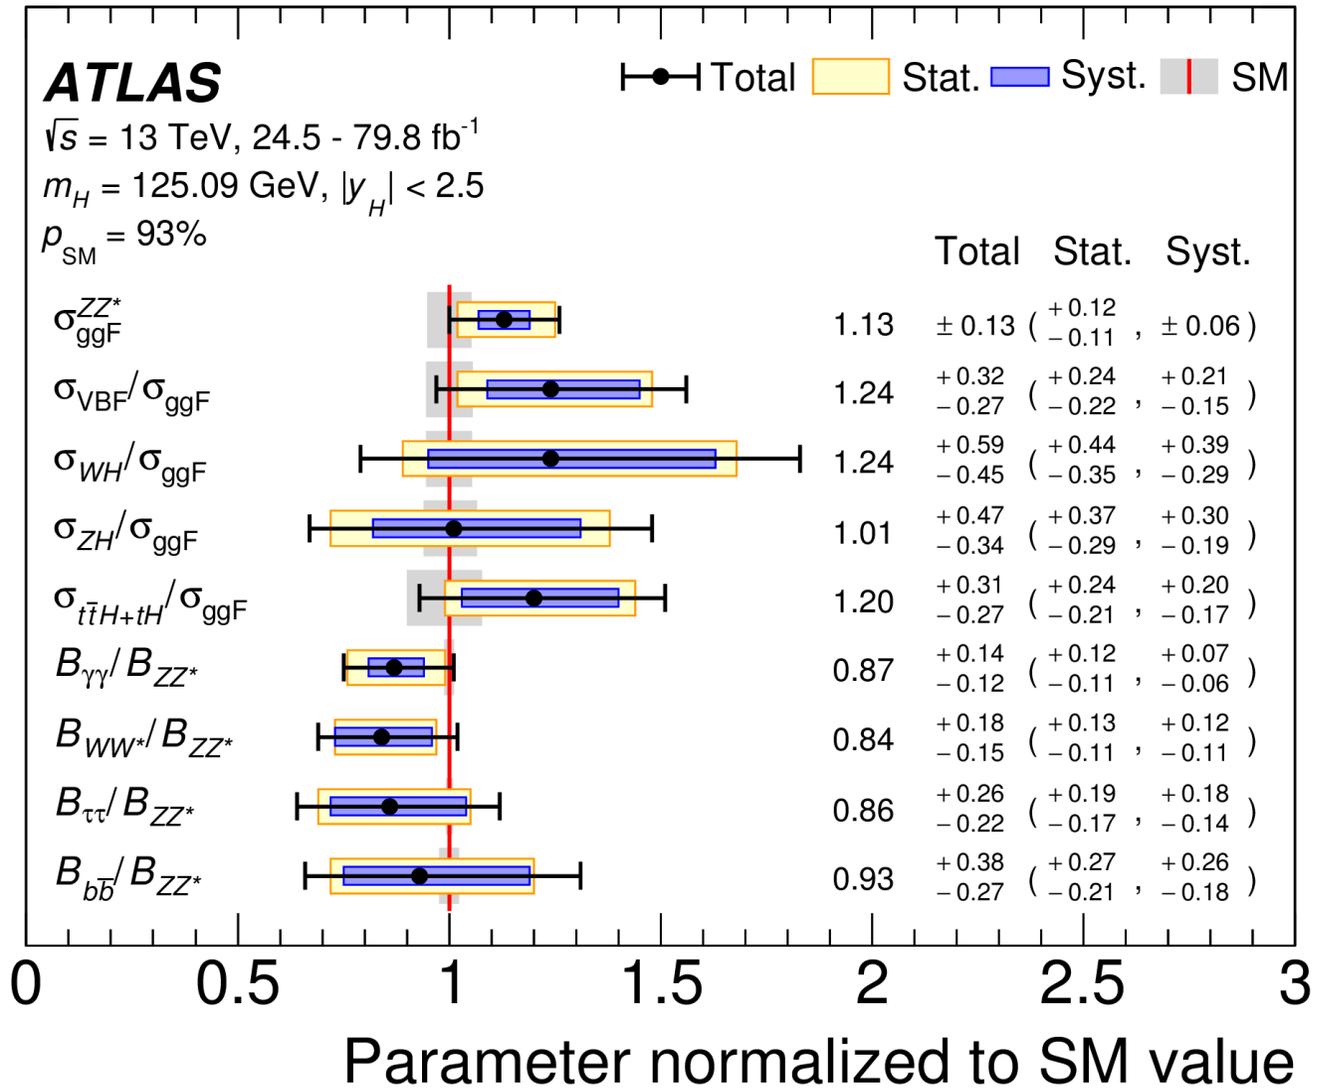

Finally if all deviations are included in a single parameter

$$\mu = 1.09 \pm 0.07 \pm 0.04(\text{expt}) \pm 0.03(\text{th. bkg}) \pm 0.07(\text{th. sig})$$

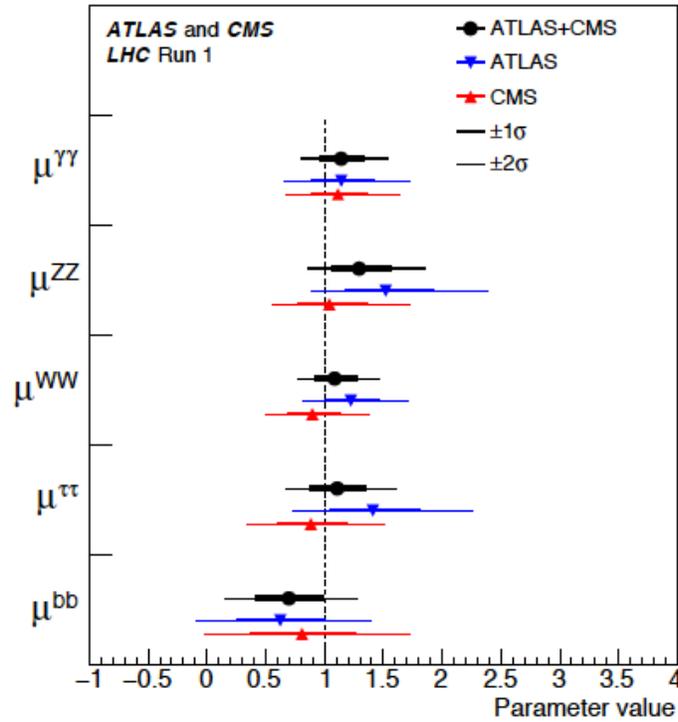

ATLAS Recent Results: references

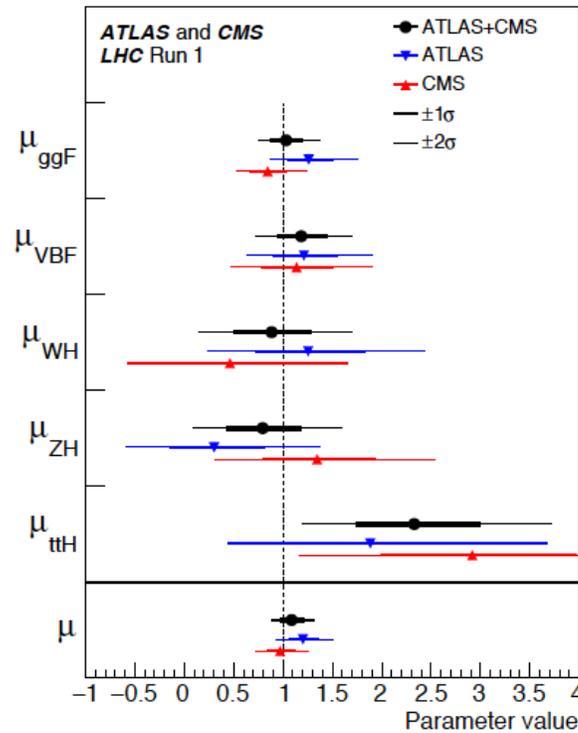

$$\sigma_{ggF}^{ZZ^*} = ggF \rightarrow H \rightarrow ZZ^*$$

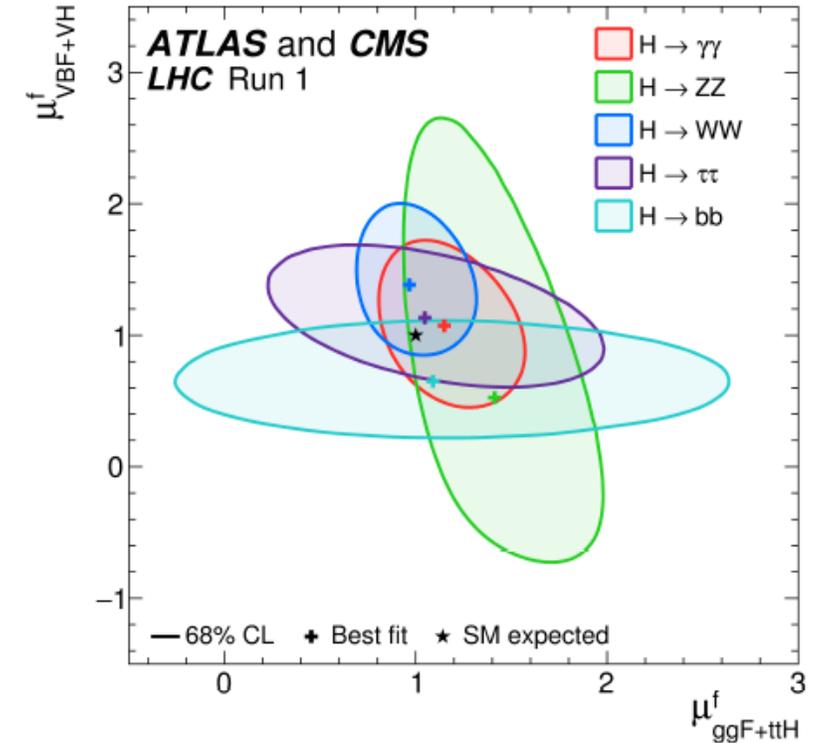

More Simplifications.. Fewer Parameters

Assume all production cross sections are SM ones \rightarrow fit only modifiers of BR's

Assume all BRs are SM ones \rightarrow fit only modifiers of production cross-sections

One more assumption: vertices with bosons VBF & VH scale with one μ and those with fermions ggF and ttH with another μ

No (significant) deviation observed so far, need more statistics ! \rightarrow LHC at High Luminosity

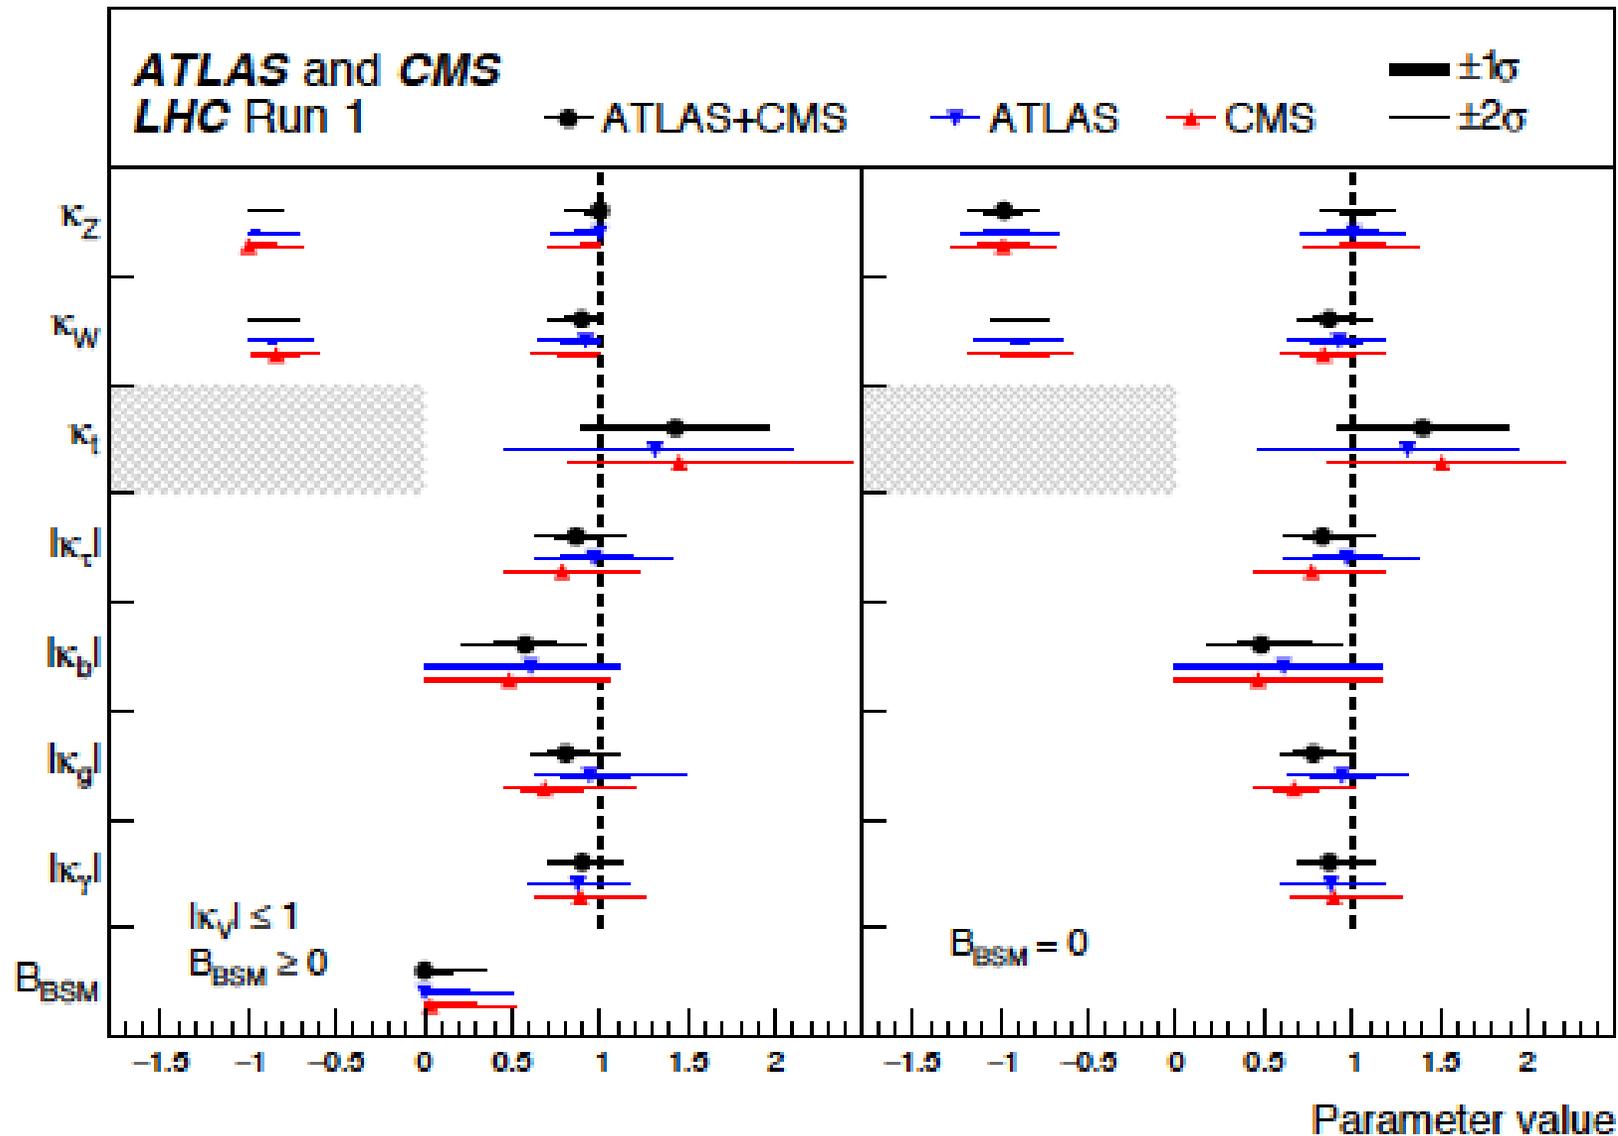

A Different Approach

Elaborate even more: introduce modifiers κ_x of vertices in the Lagrangian.
In this way production and decay vertices are treated in the same way.

$$\begin{aligned}\mathcal{L} = & \boxed{\kappa_3} \frac{m_H^2}{2v} H^3 - \boxed{\kappa_Z} \frac{m_Z^2}{v} Z_\mu Z^\mu H + \boxed{\kappa_W} \frac{2m_W^2}{v} W_\mu^+ W^{-\mu} H \\ & + \boxed{\kappa_g} \frac{\alpha_s}{2\pi v} G_{\mu\nu}^a G^{a\mu\nu} H + \boxed{\kappa_\gamma} \frac{\alpha}{2\pi v} A_{\mu\nu} A^{\mu\nu} H + \boxed{\kappa_{Z\gamma}} \frac{\alpha}{\pi v} A_{\mu\nu} Z^{\mu\nu} H \\ & + \boxed{\kappa_{VV}} \frac{\alpha}{2\pi v} \left(\cos^2 \theta_W Z_{\mu\nu} Z^{\mu\nu} + 2 W_{\mu\nu}^+ W^{-\mu\nu} \right) H \\ & - \left(\boxed{\kappa_t} \sum_{f=u,c,t} \frac{m_f}{v} f\bar{f} + \boxed{\kappa_b} \sum_{f=d,s,b} \frac{m_f}{v} f\bar{f} - \boxed{\kappa_\tau} \sum_{f=e,\mu,\tau} \frac{m_f}{v} f\bar{f} \right) H.\end{aligned}$$

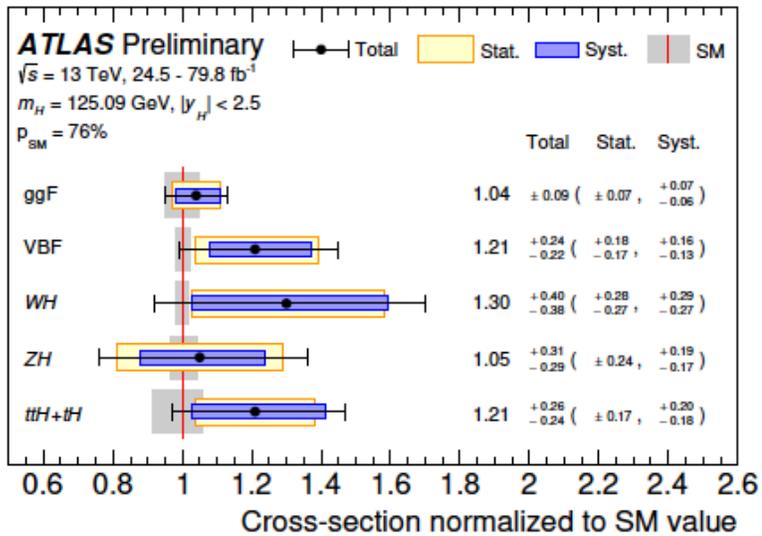

- Quadratic dependence on bosons \rightarrow +/- solutions
- Linear dependence of fermions

Conclusions

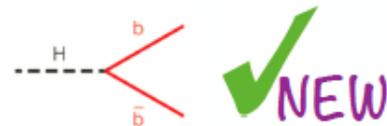

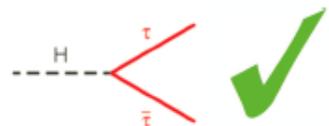

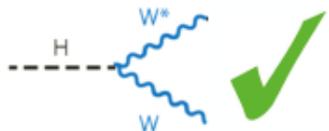

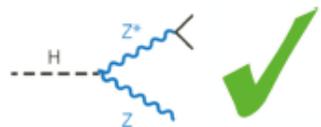

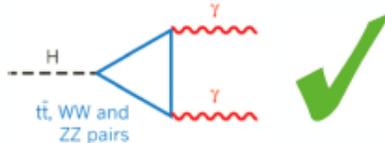

ATLAS and CMS

Production

✓ = observed

Decays

- Thanks to the first 36-80 fb⁻¹ of Run-2 data:
 - The bosonic decay channels entered a precision era (~3x improvement w.r.t. Run-1)
 - Direct observation achieved for all main production and decay modes!
 - Direct confirmation of coupling to all 3rd generation fermions (top-quark, **bottom-quark**, taus)
 - Sensitivity to double Higgs production approaching 10 x SM Higgs to 2 Higgses
- Higgs physics an important indirect probe for New Physics: so far no deviations from SM...
- But still at the beginning of a long journey! Only analyzed <3% of the final LHC luminosity.
